Teacher's Introduction

This guide has been produced specifically to support learning of the AQA GCSE (9–1) Computer Science specification, with first examinations in summer 2022.

As the specification is split into eight sections, this guide has been split into eight chapters, with content precisely mirroring the order of topics in the specification. As such, it is quite straightforward for learners to keep track of where they are in the material, and what remains to be done. The checklists, which are intended as a working document, are also useful in this regard.

Remember!

Always check the exam board website for new information, including changes to the specification and sample assessment material.

Each chapter contains, along with the theory material and illustrations, a series of exam-style questions with model answers and commentaries. Throughout the guide, a full range of question types is covered, from single-word answers and definitions to long-answer descriptions and discussions.

In terms of algorithms and programming, the AQA standard version of pseudocode is used throughout this guide, supplemented by Python code where relevant. Some key differences between Python, C# and VB.NET are also highlighted.

One chapter can be distributed to students each week or fortnight, and can be used to supplement taught material by aiding such homework/classwork tasks as providing written summaries of a chapter and/or completing the end-of-chapter questions.

More imaginative supplementary tasks that can use this guide as a starting point include the following (you may want to build some or all of these into a weekly routine, each week focusing on a different chapter):

- Providing students with lines from the appropriate section of the specification and asking them to treat each line as if it were a question. The structure of this guide can aid them in locating the answer.
- Asking students to produce five multiple-choice questions based on each chapter. Each question they produce needs to contain a correct answer, three realistic wrong answers and an indication of which answer they believe is correct. The better sets of questions can be archived to produce a half-term multiple-choice quiz, generated by students.
- Asking students to produce a mind map of each chapter as a means of aiding revision. Where applicable, Venn diagrams, flow charts and other graphic organisers can be used in this way.
- Dividing students into groups to deliver presentations on different areas of a chapter. If the group is fairly mature, these presentations can be peer-assessed.
- Using this guide as the basis for flipped learning.

I hope this guide proves useful to both teachers and students.

May 2023

Paper 2: Computing concepts

3.3. Fundamentals of Data Representation

- ☐ Define the term 'number base'
- ☐ Use decimal, hexadecimal and binary number bases and convert between them
- ☐ Explain the use of hexadecimal in computer science
- ☐ Use binary to represent whole numbers
- ☐ Define the term 'number base'
- ☐ Convert between each of the following:
 - ☐ Bit ☐ Megabyte
 - ☐ Byte ☐ Gigabyte
 - ☐ Kilobyte ☐ Terabyte
- ☐ Perform addition on up to three binary numbers
- ☐ Carry out and understand left and right binary shifts
- ☐ Define the terms 'character set', 'ASCII' and 'Unicode'
- ☐ Describe the way in which images are stored as a sequence of bits
- ☐ Describe the effect of colour depth and image size on the quality of an image
- ☐ Calculate storage requirements of image files
- ☐ Convert between binary data and a bitmap image in both directions
- ☐ Define the term 'analogue' in the context of sound
- ☐ Define the terms 'sampling', 'sampling rate' and 'sample resolution'
- ☐ Calculate storage requirements of sound files
- ☐ Define 'data compression' and explain why it is necessary
- ☐ Explain Huffman coding and interpret a Huffman tree
- ☐ Calculate storage requirements of compressed and uncompressed data
- ☐ Explain and implement run length encoding

3.4. Computer Systems

- ☐ Define the terms 'hardware' and 'software'
- ☐ Construct truth tables for AND, OR, XOR and NOT, as well as combinations of these
- ☐ Create and interpret diagrams using AND, OR, XOR and NOT logic
- ☐ Write Boolean expressions using appropriate symbols for AND, OR, XOR and NOT
- ☐ Convert between a Boolean expression and a logic circuit in both directions
- ☐ Distinguish between system software and application software
- ☐ Outline the role of operating systems in managing the following:
 - ☐ Processors ☐ Memory
 - ☐ Input and output devices ☐ Applications
 - ☐ Security
- ☐ Describe the differences between high-level and low-level programming
- ☐ Explain the need for code translation
- ☐ Compare interpreters, compilers and assemblers
- ☐ Outline the von Neumann architecture
- ☐ Explain the roles of the following components:
 - ☐ Arithmetic Logic Unit ☐ Control Unit
 - ☐ Clock ☐ Bus
 - ☐ Register
- ☐ Explain the fetch-execute cycle
- ☐ Explain the roles of, and differences between, the following components:
 - ☐ RAM ☐ ROM
 - ☐ Cache ☐ Register
- ☐ Explain the need for secondary storage
- ☐ Explain the operation of solid-state, magnetic and optical storage
- ☐ Describe the nature, advantages and disadvantages of cloud storage
- ☐ Describe the nature of embedded systems, with examples

3.1. Fundamentals of Algorithms

3.1.1. Representing Algorithms

Algorithm – a sequence of steps that can be followed to complete a task. It is not a computer program, although a computer program is one way of representing an algorithm. For example, if you were to follow a recipe to bake a cake, you will have to follow the steps without using a computer.

Decomposition – breaking down a problem into smaller 'sub-problems' that each accomplish a clear and specific task. This has a number of advantages:

- Smaller problems are easier to solve than larger problems
- Each sub-problem can be developed separately, making planning and implementation easier
- Sub-problems are easier to distribute among a team than one large problem
- If a sub-problem is too complex to solve in isolation, it can be delegated to someone else

Abstraction – removing unnecessary detail from the problem in order to focus on the essential elements to understand and solve.

Commonly used methods of defining algorithms include **pseudocode**, **flowcharts** and **natural language**.

The exam might contain questions on any combination of these methods. One way to prepare for this is to practise converting between them. Try turning a flowchart into pseudocode or vice versa.

Pseudocode – a cross between English and a generic-looking programming language. Pseudocode would not compile, a competent programmer could convert it into a real programming language.

A pseudocode algorithm for selling tickets might be as follows. Larger purchases are given a discount of 3.45 per ticket:

```
OUTPUT "How many tickets?"
tickets ← USERINPUT
IF tickets > 5 THEN
    OUTPUT tickets * 3.45
ELSE
    OUTPUT tickets
ENDIF
```

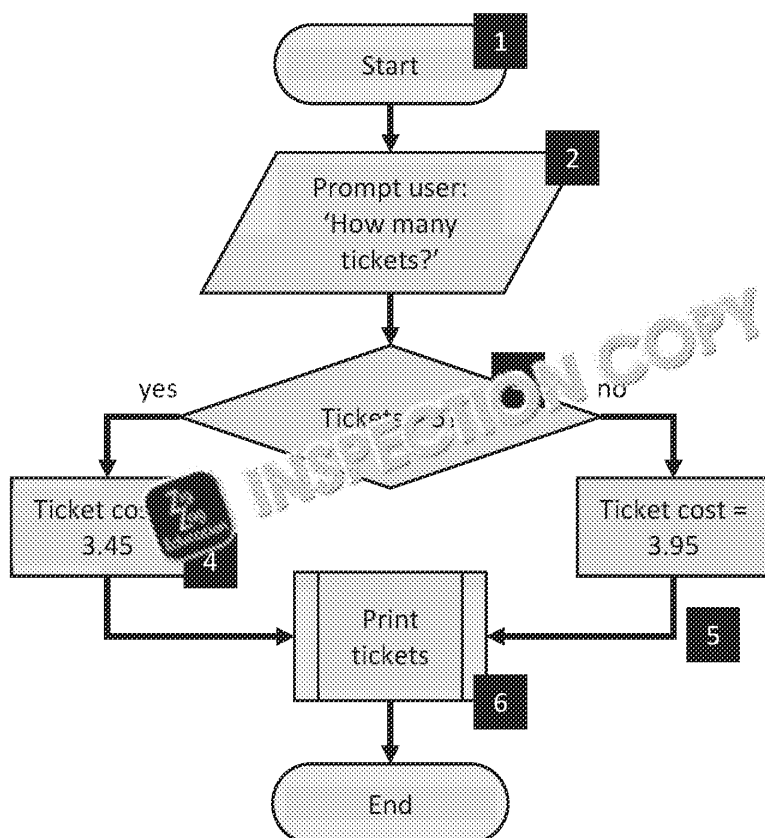

Flowchart – a means of defining an algorithm using shapes and arrows. Steps in the algorithm are represented using specific shapes, and the directions of flow are indicated by arrows.

INSPECTION COPY

COPYRIGHT
PROTECTED

A flowchart does the same job as pseudocode in defining an algorithm, but it is more visual and is easier for someone who is not a programmer. The flowchart segment below defines a similar part of the algorithm as the pseudocode above, but it looks very different:

1. Terminator – used to start and end a flowchart and one is used else.
2. Input/output – used when data is entering or leaving the system. It is written in this shape.
3. Decision – used to make a choice between two or more available answers. It is written in this shape.
4. Process – used to perform an instruction. It is common to use a rectangle with a double vertical line on the left side.
5. Arrow – used to connect the steps in the flowchart. It is used to show the flow of events taking place.
6. Subprogram – used when a subprogram is called. It is written in this shape. This allows the flowchart to be divided into sections.

Program code – another means of defining an algorithm is to simply write the code in a programming language. If you're programming in Assembly or machine code, you're using a high-level language. Other languages include Python, Visual Basic, Java and C#. Although it's quicker to go straight to the programming language, designing first using flowcharts or pseudocode can reduce errors.

Trace Tables

You may be provided with an algorithm in pseudocode, and asked what it does or what the output will be. To do this, you need to be able to read and understand algorithms.

```

1  number ← 3
2  result ← 1
3  WHILE number > 1
4      result ← result + number
5      number ← number - 1
6  ENDWHILE
7  OUTPUT result
  
```

When interpreting an algorithm, you need to think about what the computer would do. A trace table should be used to keep track of the variables that change throughout the algorithm. The variables in this pseudocode are 'number' and 'result'.

**COPYRIGHT
PROTECTED**

| number | result | output | Commentary |
|--------|--------|--------|---|
| 3 | 1 | | In lines '1' and '2', the variables are given these values. |
| 3 | 1 | | In line 3, which is the start of a loop, we are told that 'number' is greater than '1'. Since 'number' is '3', the loop runs. |
| 3 | 3 | | In line 4, 'result' is set to itself multiplied by 'number'. '1' times '3' is '3'. |
| 2 | 3 | | Line 5 says that 'number' should have 1 subtracted from it. |
| 2 | 3 | | Line 6 marks the end of the loop, so we go back to line 3. |
| 2 | 3 | | 'number' is still greater than '1', so the loop runs again. |
| 2 | 6 | | In line 4, 'result' is set to itself multiplied by 'number'. '3' times '3' is '6'. |
| 1 | 6 | | 'number' is reduced by '1' again on line '5'. |
| 1 | 6 | | Line 6 marks the end of the loop, so we go back to line 3. |
| 1 | 6 | | The loop will not run a third time because 'number' ('1' is not greater than '1'), so we jump to the first line after the loop. |
| 1 | 6 | 6 | 'result' is displayed, which is currently '6'. |

Looking at an algorithm as a whole can be daunting, but following it one line at a time is a good deal simpler; no individual line is particularly complicated, and errors can be spotted more easily.

As for what this algorithm does, it provides you with the **factorial** of 'number'. A factorial of a whole number is calculated like this:

Factorial 3: $3 * 2 * 1 = 6$
 Factorial 4: $4 * 3 * 2 * 1 = 24$
 Factorial 5: $5 * 4 * 3 * 2 * 1 = 120$

In Python, one way to implement this algorithm would be as follows:

```
number = input("Enter a number: ")
answer = 1
while number > 1:
    answer = answer * number
    number = number - 1
print(answer)
```

The same algorithm in pseudocode would be as follows:

```
OUTPUT 'Enter a number: '
number ← input
answer ← 1
WHILE number > 1
    answer ← answer * number
    number ← number - 1
ENDWHILE
OUTPUT answer
```

**COPYRIGHT
PROTECTED**

3.1.2. Efficiency of Algorithms

Efficiency – a measure of comparing two different algorithms that solve the same problem. The more efficient algorithm is a better choice. Efficiency can be measured in a number of ways. At GCSE level, you need only worry about time efficiency. An algorithm that takes 10 instructions is more efficient than one that takes 30 instructions.

You may be expected to compare the efficiency of two different algorithms at sorting an array of numbers into order. When doing this, remember that a loop that repeats a block of code 10 times is more efficient than the equivalent body of code copied and pasted 10 times.

3.1.3. Searching Algorithms

Searching – determining whether a specific piece of data exists within a data structure. A search algorithm will reveal its location.

Linear search – a search algorithm that begins at one end of a data structure and examines each item in turn until the required item is found, or the end of the structure is reached.

| | | | | | | |
|---|---|---|---|---|---|---|
| 5 | 8 | 4 | 2 | 9 | 6 | 7 |
|---|---|---|---|---|---|---|

If a linear search were being used to find the number 9, the numbers 5, 8, 4, 2 are examined in order. If the number 1 were being sought, it would not be found, but each element would be examined to verify this.

If the item being searched for is found, the code returns the location within the data structure. The first location is numbered '0', the second '1', the third '2', and so on:

| | | | | | | |
|---|---|---|---|---|---|---|
| 5 | 8 | 4 | 2 | 9 | 6 | 7 |
| 0 | 1 | 2 | 3 | 4 | 5 | 6 |

Binary search – a search algorithm that begins in the middle of a data structure and repeatedly divides the remaining data with each pass. Binary searches are only appropriate for sorted data structures.

A binary search for the number 9 in a different collection of values:

| | | | | | | |
|---|---|---|---|---|----|----|
| 2 | 4 | 5 | 8 | 9 | 11 | 15 |
|---|---|---|---|---|----|----|

The value in the middle is 8; the value we are searching for is larger than that and so we know it must be found somewhere to the right of 8. Consequently, the 8, and everything to its left, can be ignored.

| | | | | | | |
|---|---|---|---|---|----|----|
| 2 | 4 | 5 | 8 | 9 | 11 | 15 |
|---|---|---|---|---|----|----|

COPYRIGHT
PROTECTED

There are now three elements to be searched through. Again, the binary search elements can be disregarded because they can only contain numbers larger than

The number we were searching for has been found. If we were searching for a different number, we could conclude at this point that this number isn't present, without needing to check the rest of the data. Binary searches are quicker because, at each stage, half of the remaining data is discarded. If one million elements was to be searched using a binary search, it would take no more than 20 iterations. A particular piece of data or to discover that the data is not contained within the array of items would only require 30 iterations.

A binary search is more efficient than a linear search, since it will, on average, find the data more quickly than a linear search. However, binary searches do not work on unsorted data, which is a consideration.

| Linear Search | Binary Search |
|--|----------------------------------|
| + Functions on unsorted data | + Far more time efficient |
| - More time-consuming than a binary search in most instances | - Will not work on unsorted data |

Although a binary search usually executes more quickly than a linear search, the linear search would be more efficient if the data being sought appears first in its data structure, a linear search would attempt, whereas a binary search would not.

3.1.4. Sorting Algorithms

Sorting – putting data into order, whether that be numerical order, alphabetical (A–Z) or descending (Z–A) – or chronological order.

Not sorted:

| | | | | | | |
|---|---|---|---|---|---|---|
| 5 | 8 | 4 | 2 | 9 | 6 | 7 |
|---|---|---|---|---|---|---|

Sorted:

| | | | | | | |
|---|---|---|---|---|---|---|
| 2 | 4 | 5 | 6 | 7 | 8 | 9 |
|---|---|---|---|---|---|---|

There are several different methods for putting data items into order, and here we will look at two:

- Bubble sort
- Merge sort

There is no 'best' sort algorithm, and it's always good, as a programmer, to attempt to solve any problem.

Bubble sort

(4 2 7 5 3) ← Unsorted data set

First pass

(2 4 7 5 3) ← The 2 and the 4 have been switched, as 4 is greater than 2

(2 4 7 5 3) ← The 4 and the 7 are not switched, as they are already in the correct order

(2 4 5 7 3) ← The 5 and the 7 are switched, as 7 is greater than 5

(2 4 5 3 7) ← The 3 and the 7 are switched, as 7 is greater than 3

Second pass

(2 4 5 3 7) ← The 2 and the 4 are not switched, as they are already in the correct order

(2 4 5 3 7) ← The 4 and the 5 are not switched, as they are already in the correct order

(2 4 3 5 7) ← The 3 and the 5 are switched, as 5 is greater than 3

(2 4 3 5 7) ← The 5 and the 7 are not switched, as they are already in the correct order

Third pass

(2 4 3 5 7) ← The 2 and the 4 are not switched, as they are already in the correct order

(2 3 4 5 7) ← The 4 and the 3 are switched, as 4 is greater than 3

(2 3 4 5 7) ← The 4 and the 5 are not switched, as they are already in the correct order

(2 3 4 5 7) ← The 5 and the 7 are not switched, as they are already in the correct order

At this stage, the list is sorted, but one more pass would be performed because a complete pass has yielded no changes. In the worst case, $n-1$ (n being the number of elements) passes are taken place.

**COPYRIGHT
PROTECTED**

Merge sort

| | | |
|---------------------------------|---|--|
| (4 9 5 1 3 2 7 8) | ← | Unsorted data set |
| (4) (9) (5) (1) (3) (2) (7) (8) | ← | Data is split into individual units |
| (4 9) (5) (1) (3) (2) (7) (8) | ← | The first pairing, 4 and 9, is brought together |
| (4 9) (1 5) (3) (2) (7) (8) | ← | The next pairing is 5 and 1, whose positions are swapped |
| (4 9) (1 5) (2 3) (7 8) | ← | In this way, all data are merged into sorted pairs |

Next, the pairs must be merged into groupings of four. We'll look at the first two.

(4 9) (1 5)

The values '4' and '1' are compared. Since '1' is the first within their respective pairings, the four must be one of these two.

(4 9) (1 5) → (1)

Next, the first remaining value in each pairing is compared with the other. Value '4' is less than '5', so the order remains the same.

(4 9) (1 5) → (1 4)

At any given point, two numbers are examined, with the next in order being added to the set. The copy is always in order:

(4 9) (1 5) → (1 4 5 9)

The same principle is applied to the other two pairings to leave two sorted clusters of four.

| | | |
|-------------------------------|---|----------------------------------|
| (1 4 5 9) (2 3 7 8) | ← | Two sorted clusters of four data |
| (1 4 5 9) (2 3 7 8) (1) | ← | '1' and '2' were compared |
| (1 4 5 9) (2 3 7 8) (1 2) | ← | '4' and '2' were compared |
| (1 4 5 9) (2 3 7 8) (1 2 3) | ← | '4' and '3' were compared |
| (1 4 5 9) (2 3 7 8) (1 2 3 4) | ← | '4' and '7' were compared |

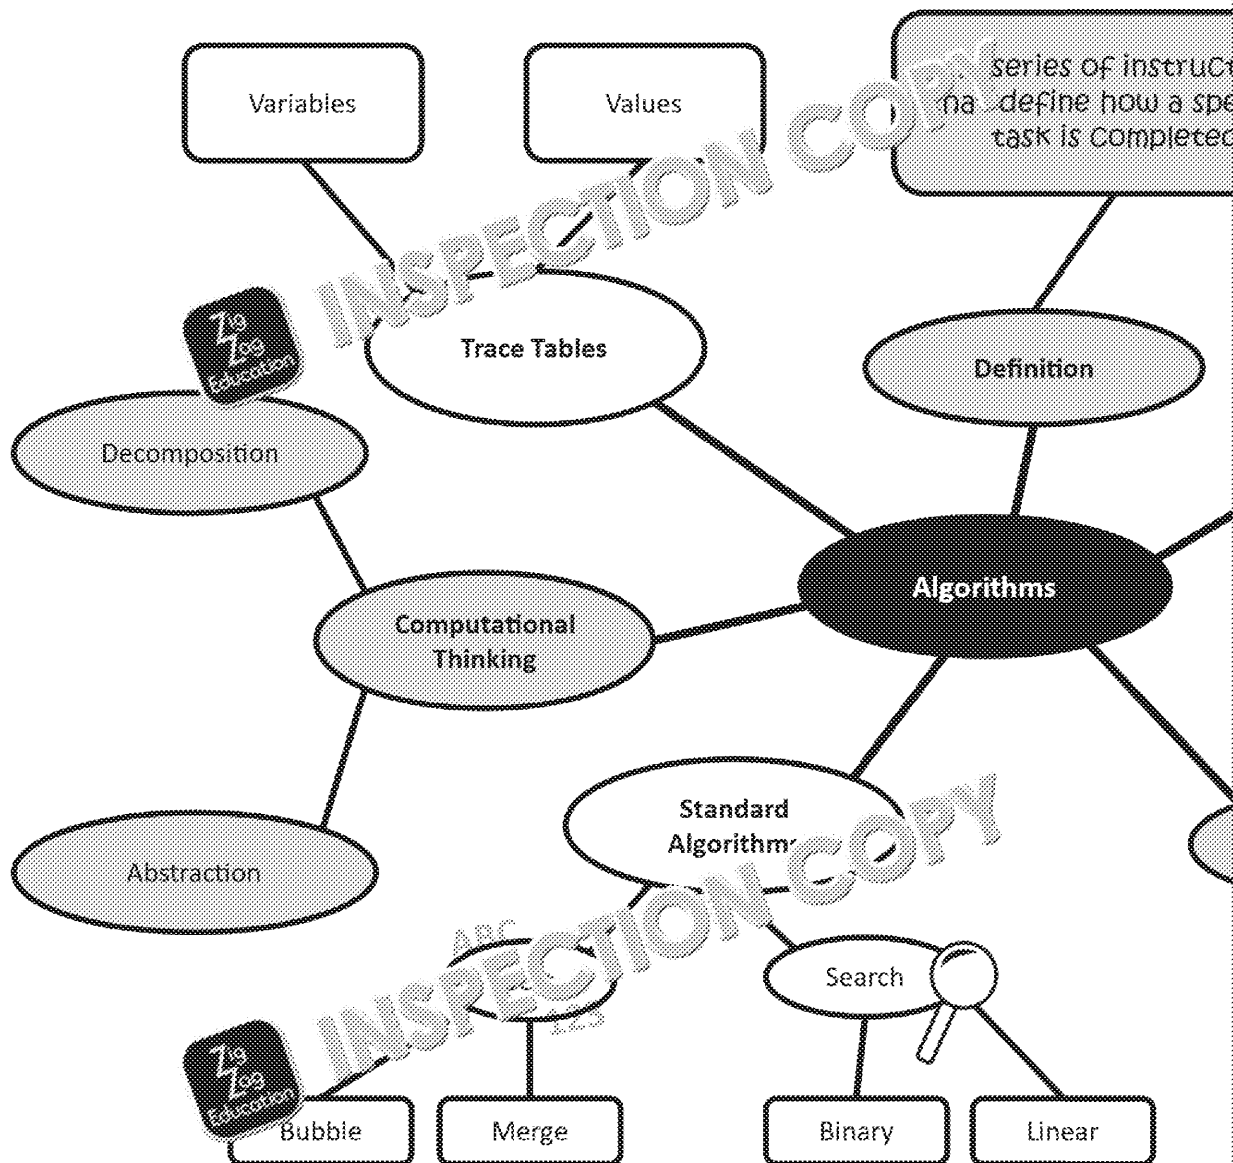

Eventually, this would result in a single, sorted data set, comprising eight data items. This process is repeated to sort a data set containing any number of data items.

| Bubble Sort | |
|--|--|
| + Straightforward to program | More efficient in terms of time |
| + Does not use much extra memory space while the sort is in progress | |
| - Can take a very long time with a large set of data to sort | - More complex to program - Requires lots of memory |

3.2. Programming

3.2.1. Data Types

Each item of data is of a particular type. Some types are numeric, and others are of data determines the operations that can be performed upon it. For example, $x + y$ and a real, but not a Boolean and a string.

| Data Type | Description | Use in Python | Use in VB.Net |
|-----------|--|--|--|
| Boolean | Can be either true or false. | <code>bn = True</code> | <code>Dim bn as Boolean bn = true</code> |
| Character | A single letter, number, punctuation mark, etc. | Python does not have a 'character' data type, but most other languages do. | <code>Dim cr as Character cr = 'a'</code> |
| Integer | Whole numbers – positive, negative or zero. | <code>i = 5</code> | <code>Dim i as Integer i = 5</code> |
| Real | Decimal numbers – positive or negative (zero can also be stored in a 'real' variable). | <code>pi = 3.142</code> | <code>Dim pi as Single pi = 3.142</code> |
| String | A collection of characters used to store names, addresses, phone numbers, etc. | <code>name = "Bob"</code> | <code>Dim name as String name = "Bob"</code> |

3.2.2. Programming Concepts

Variable – a named space in memory, large enough to store a single piece of data of a data type. Although some languages, including Python, do not require a data type, each variable still has one.

Constant – a named space in memory with a value that can never change while running. Useful for π (which will never change) or VAT (which seldom changes). Although some languages do not allow for constants, but other languages do.

C#: `float vat = 0.2F;`
VB.Net: `Const vat as Single = 0.2`

Assignment – the process of putting a value into a variable. Most languages do this. In the instruction `x = 5`, the value '5' has been assigned to x.

Programming Constructs

Sequence

Sequence means that instructions will always execute in the order in which they are written and be executed once and only once.

```
hourlyRate ← USERINPUT
hours ← USERINPUT
OUTPUT hourlyRate * hours
```

This program asks for the hourly rate and the number of hours worked before the figures are multiplied. At this point, the program ends.

Selection

Selection is when one path through the code is chosen where multiple possibilities exist. The word 'if' is the most common indicator of selection, although there are other words used.

```
hours ← USERINPUT
rate ← USERINPUT
IF hours > 40 THEN
    OUTPUT 'Normal Earnings: ' + (40 * rate)
    OUTPUT 'Overtime Earnings: ' + ((hours - 40) * rate)
ELSE
    OUTPUT 'Normal Earnings: ' + (hours * rate)
    OUTPUT 'No Overtime'
ENDIF
```

The first two lines will always run; the program asks the user for the number of hours and the hourly rate, storing each value in a separate variable. Then a decision is made. If 'hours' is greater than 40, the first two indented lines will run. Otherwise, the last two indented lines will run. There is no 'else' when all four would be executed.

Condition-controlled (indefinite) iteration

Iteration means 'looping'. Code that is iterative might be executed multiple times. The code is written once.

```
looping ← True
WHILE looping = True
    hourlyRate ← USERINPUT
    hours ← USERINPUT
    OUTPUT hourlyRate * hours
    yesOrNo ← USERINPUT
    IF yesOrNo = 'no' THEN
        looping ← False
    ENDIF
ENDWHILE
```

The second line specifies the condition that will make the rest of the code loop until the 'looping' variable is set to false.

Nesting – this involves placing one programming structure inside another. For example, a loop contains an IF structure (on the penultimate line) that is **nested** within the loop. Additional nesting is also possible; that IF structure could have contained a loop which itself contained another WHILE structure...

INSPECTION COPY

COPYRIGHT
PROTECTED

Count-controlled iteration

The above code loops until the user enters the letter 'n'. It is impossible to know how many times the loop will run. Sometimes, code is required that runs a predetermined number of times.

```
FOR x ← 1 to 12
    OUTPUT x * 2
ENDFOR
```

This code will run 12 times, with the variable 'x' taking the values 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12. The purpose of this code is to display the two times table.

Pre-check iteration – the condition that determines whether the code will loop again is placed at the start of the structure. If this condition is false, the code within the iteration structure will never run:

```
WHILE x < 5
    ...
ENDWHILE
```

Post-check iteration – the condition that determines whether the code will loop again is placed at the end of the structure. This means the code will always run at least once, as it will run on the first pass without needing to check the condition.

```
REPEAT
    ...
UNTIL x >= 5
```

When you write program code, you should make use of **meaningful identifiers**. Anything you give to anything, such as a variable, should clearly identify its purpose. A variable name should be as meaningful as a variable named `player1Score`. Meaningful identifiers are used by all other programmers who may need to work on your code.

3.2.3. Arithmetic Operations in a Programming Language

Operator – in the context of computer science, an operator performs operations on pieces of data in order to produce additional data. There are **arithmetic operators** and **Boolean operators**.

Arithmetic operator – performs a process on one or more numbers. The basic arithmetic operators are: `+` `-` `*` `/`

| Pseudocode | Explanation |
|----------------------------------|--|
| <code>total ← 10 + 5</code> | Addition (15) |
| <code>result ← 10 - 5</code> | Subtraction (5) |
| <code>product ← 5 * 10</code> | Multiplication (50) |
| <code>answer ← 10 / 5</code> | Division (2) |
| <code>outcome ← 13 DIV 5</code> | Quotient, also known as integer division (2) |
| <code>solution ← 13 MOD 5</code> | Modulo (3) – divides but uses only the remainder |

COPYRIGHT
PROTECTED

3.2.4. Relational Operations in a Programming Language

Relational operator – a comparison between two values to check, for equal, or whether one is less than or greater than the other. Relational statements and as part of loops.

| Pseudocode | Example |
|-------------------------------------|---|
| IF $x > y$ THEN ... ENDIF | If 'x' is greater than 'y' |
| WHILE $a < b$... ENDWHILE | While 'a' is less than 'b' |
| IF $q \geq r$ THEN ... ENDIF | If 'q' is either greater than or equal to 'r' |
| WHILE $j \leq k$... ENDWHILE | While 'j' is either less than or equal to 'k' |
| IF $e = f$ THEN ... ENDIF | If 'e' and 'f' are equal. |
| WHILE $m \neq n$... ENDWHILE | While 'm' and 'n' are not equal. |

INSPECTION COPY

COPYRIGHT
PROTECTED

3.2.5. Boolean Operations in a Programming Language

Boolean operator – a logic expression can have one of only two outcomes. A Boolean operator connects together logic expressions to produce a more complex logic expression. AND and OR are the most commonly used logic operators.

| Python Code | Explanation |
|--|--|
| <code>if (age > 15 and age < 65):</code> | Age has to be both above 15 <i>and</i> below 65. The contents of this IF structure would only execute if both conditions are true. |
| <code>if (age < 16 or age > 64):</code> | The contents of this IF structure would execute if the age is below 16 <i>or</i> above 64. |
| <code>if (not (age < 16)):</code> | <code>not</code> translates to 'if age is <i>not</i> less than 16'. It also translates the outcome of a logic expression to 'false' or from 'false' to 'true'. |

Here is a piece of Python code that combines all three types of operator. It calculates the cost of adults and children entering a zoo. How much would it cost for two adults and one child?

```
adults = int(input("How many adults: "))
children = int(input("How many children: "))

if (adults + children >= 5) or (adults >= 2):
    cost = adults * 9 + children * 4.5
else:
    cost = adults * 10 + children * 5
print(cost)
```

Here is the same functionality represented using pseudocode:

```
adults ← USERINPUT
children ← USERINPUT

IF (adults + children >= 5) OR (adults >= 2) THEN
    cost ← adults * 9 + children * 4.5
ELSE
    cost ← adults * 10 + children * 5
ENDIF
OUTPUT cost
```

COPYRIGHT
PROTECTED

3.2.6. Data Structures

Data structure – a structured (organised) means of storing related data. To store a single piece of data, a data structure can contain many.

Many data structures exist, and it's even possible to invent your own. In GCSE Computer Science, you will be familiar with **one-dimensional arrays**, **two-dimensional arrays** and **records**.

One-dimensional array – a data structure for storing multiple data items. Think of a one-dimensional array as a row of variables. Instead of each variable having its own name, the whole array has a single name, while each **element** in the array has an individual name. A one-dimensional array might store a pupil's most recent sports scores.

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---|---|---|---|---|---|---|---|
| | | | | | | | |

The first element is always numbered '0', so the array above contains eight empty slots for scores stored in each of the empty boxes.

| Python Code | Explanation |
|---|--|
| <code>myArray = [4, 6, 1, 2, 9, 0]</code> | Creates an array called 'myArray' and populates it with the values 4, 6, 1, 2, 9, and 0. |
| <code>myArray[0] = 5</code> | Places the number '5' into the first element of the array. |
| <code>print(myArray[2])</code> | Displays the third element of the array – 1. |

Two-dimensional array – a data structure for storing multiple data items. It is much like a one-dimensional array, but can be considered as a grid rather than a row.

| | | | |
|------|------|------|------|
| 0, 0 | 0, 1 | 0, 2 | 0, 3 |
| 1, 0 | 1, 1 | 1, 2 | 1, 3 |
| 2, 0 | 2, 1 | 2, 2 | 2, 3 |

Elements are referred to, as seen here, with two numbers, much like a grid. If the grid were larger, it could be used as a grid for a computerised game of noughts and crosses.

| Python Code | Explanation | | | | |
|--|--|---|---|---|---|
| <code>myArray2 = [["a", "b"], ["c", "d"]]</code> | Create a two-dimensional array with two rows and two columns. <table border="1"> <tr> <td>a</td><td>b</td></tr> <tr> <td>c</td><td>d</td></tr> </table> | a | b | c | d |
| a | b | | | | |
| c | d | | | | |
| <code>myArray2[1][0] = "z"</code> | It might help to visualise it in a grid. The computer does not store arrays in a grid. This would replace 'c' with 'z'. | | | | |
| <code>print(myArray2[0][1])</code> | Displays the requested letter 'b'. | | | | |

COPYRIGHT
PROTECTED

Record – a data structure that can accept multiple data items that do not have the same data type. As far as Python is concerned, there is no difference between lists and records. Records are managed in the same way. One record might store a student's name and test score. The next record would store the same details for another student.

| Python Code | Explanation |
|--|--|
| <code>student1 = ["Bob", 8, 89.2]</code> | Creates a record called 'student1'; |
| <code>student1[1] = 9</code> | 'Bob' has been moved from year 8 to year 9 |
| <code>print(student1[2])</code> | Displays 89.2 – Bob's average test score |

If you are asked to name a suitable data structure for a specific situation, it can be an array (at least this is true at GCSE level). If the data structure is going to store data of different types, a record is always the right choice.

3.2.7. Input/Output

Input – the process of introducing data into a computer system. In the classroom, the keyboard is used as the input device.

Output – the process of communicating data beyond the system, typically to the user. In the classroom, the visual display unit (VDU) will be used as the output device.

| Python Code | Explanation |
|--|--|
| <code>name = input("Name: ")</code> | Asks the user for the name and stores it in a variable called <code>name</code> |
| <code>age = int(input("Age: "))</code> | Asks the user for the age and stores it as an <i>integer</i> in a variable called <code>age</code> |
| <code>height = float(input("Height (m): "))</code> | Asks the user for the height and stores it as a <i>real</i> number in the variable called <code>height</code> |
| <code>print("hello")</code> | Displays the text <code>hello</code> on the screen |
| <code>print(hello)</code> | Without the speech marks, Python will look for the name of a variable called <code>hello</code> and display the value stored in it |

3.2.8. String Handling Operations in a Programming Language

| Python Code | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| <pre>firstName = "Richard" lastName = "Lee" fullName = firstName + " " + lastName</pre> | The third line uses strings (join them together). The concatenated variable, 'fullName', contains the person's first and last names, or locations, or entered data. | | | | | | | | |
| <pre>firstName = "Richard" print(len(firstName))</pre> | Displays the length of the string. This would output 8. | | | | | | | | |
| <pre>fullName = "Richard Lee" print(fullName.index(" "))</pre> | Looks for one string character in the code. This code will look for the first occurrence of 'Richard Lee'. This would output the index of the character, like this: <table><tr><td>0</td><td>1</td><td>2</td><td>3</td></tr><tr><td>R</td><td>i</td><td>c</td><td>h</td></tr></table> The space is in position 7. This would be output by the code. | 0 | 1 | 2 | 3 | R | i | c | h |
| 0 | 1 | 2 | 3 | | | | | | |
| R | i | c | h | | | | | | |
| <pre>fullName = "Richard Lee" print(fullName[0:7])</pre> | Displays a substring of the string. This would output 'Richard'. | | | | | | | | |
| <pre>letter = 'a' print(ord(letter))</pre> | The purpose of 'ord' is to convert a character to its ASCII code. This would display 97. | | | | | | | | |
| <pre>code = 97 print(chr(code))</pre> | This performs the chr function. This would display 'a'. | | | | | | | | |
| <pre>a = '123' b = int(a)</pre> | The variable 'a' contains a string of three numerals. The second line converts the string to the integer 123, storing that value in 'b'. | | | | | | | | |
| <pre>c = '123.456' d = float(c)</pre> | The variable 'c' now contains a real number. The second line converts the string to the float 123.456, storing it in 'd'. | | | | | | | | |
| <pre>e = 789 f = str(e)</pre> | Here, we see a variable 'e' containing an integer. The second line converts the integer to a string, storing it in 'f'. | | | | | | | | |

COPYRIGHT
PROTECTED

3.2.9. Random Number Generation in a Programming Language

Random – a random number has been selected from a range of numbers where every number in the range had an equal chance of being selected.

Random integers in Python:

```
import random          ← Imports the 'random' library, allowing random numbers to be generated
print(random.randint(0, 9)) ← Outputs a random integer between 0 and 9
```

Random numbers have many uses in computing:

- Encrypting data, making it difficult for unauthorised people to understand
- Causing simulations, such as flight simulations, to run differently every time
- Adding variability to computing, e.g. enemy units might have behaviour that changes over time
- Random sampling of survey participants, i.e. randomly selecting names from a list

3.2.10. Structured Programming and Subroutines

Subroutine – an out-of-line block of code that can be called by typing its name.

There are benefits to using subroutines to write a program:

- Each subroutine can be assigned to a different programmer, enabling teamwork
- Subroutines can be separately tested, so testing can begin long before the program is complete
- Commonly used subroutines can be reused in other programs, saving time and effort

We could break a ticketing program into the following subroutines:

In Python, the subroutines would be declared like this:

```
def promptUser():
def calculateTotal():
def displayTotal(total):
```

Parameter – a piece of data that is passed into a subroutine in order to perform a task. In the above example, 'total' is a parameter that will be passed to the 'displayTotal' subroutine. Multiple parameters can be passed to a subroutine, e.g. `def displayTotals(total1, total2, total3, etc.)`.

**COPYRIGHT
PROTECTED**

The code within a subroutine will only be run if that subroutine is **called**.

Calling – a process where an instruction in one part of the code tells another part of the code to run. If you have a subroutine called `promptUser`, the code within that subroutine will only happen without that subroutine being called.

Examples of calling subroutines:

```
promptUser()
total = calculateTotal()
displayTotal(total)
```

These three instructions tell the subroutines to happen in a particular order. Code the subroutines, so that the finished listing looks like this. Notice how spacing greatly

```
1  def promptUser():
2      global adults, children
3      adults = int(input("How many adults: "))
4      children = int(input("How many children: "))
5
6  def calculateTotal():
7      print("adults: " + str(adults))
8      if ((adults + children >= 5) or (adults >= 2)):
9          total = (adults * 9) + (children * 4.5)
10     else:
11         total = (adults * 10) + (children * 5)
12     print(total)
13     return total
14
15 def displayTotal(total):
16     print("Total cost: " + str(total))
17
18 promptUser()
19 total = calculateTotal()
20 displayTotal(total)
```

NB the numbered list below tells you the order in which things take place – these are the line numbers in the program.

1. The first line to be executed is line 18, where the `promptUser` subroutine is called. This belongs to the subroutines, which will only run when they are called.
2. Program execution jumps to lines 1–4, where the 'adults' and 'children' variables are initialised with user input. These variables are global, meaning they are accessible in all other subroutines.
3. Once lines 1–4 have been executed, control jumps back to line 18, which is where the `promptUser` call is finished. Control then jumps onto line 19. The `calculateTotal` subroutine is then called, and control now jumps to line 6.
4. Lines 6–13 calculate the total cost of entry based on the number of adults and children entered.
5. The `return` statement on line 13 passes the 'total' variable *back* to line 19, where the `calculateTotal` subroutine was called from. Whatever the value of the 'total' variable is, it is stored in the 'total' variable on line 19.
6. On line 20, the `displayTotal` method is called, with the contents of 'total' as an argument. This value (received in brackets on line 15) is then output as part of line 16.

The best way to understand code is to write it. Using this program as a template, try adding a discount code that takes 10% from the total. You may want to create a `promptForDiscountCode` subroutine.

**COPYRIGHT
PROTECTED**

The Structured Approach

When adopting a structured approach, you should take advantage of the following:

- Modularisation
- Well-documented interfaces
- Appropriate use of local variables

Modularisation – the process of breaking a program into smaller parts. A module is a type of module, and the advantages of dividing a program into either of the same.

Interface – nothing to do with the user interface. This term means some of code. The interface is how you allow other programmers to use any programming constructs that you have written. Specifically:

- Self-documenting identifiers should be used; a subroutine's name should be able to read and understand its inner workings. The subroutines' parameters and return values.
- Another programmer should not be required to understand *how* it works, *what* it does. They provide the parameters and they receive the results. The internal workings should ideally be inaccessible to them (which is actually

Scope – refers to the visibility of a variable, and can be either **local** or **global**.

| Python Code | |
|---|---|
| <pre>def setup(): global vat vat = 0.2 def sale(): price = 1.99 quantity = 5 total = price * quantity * (1 + vat) print(total) def refund(): amount = total / (1 + vat)</pre> | <p>vat is global – it is visible in all subroutines. You can see it used in 'sale' and 'refund'.</p> <p>The other variables (price, quantity, total, amount) are local within the subroutines. The last line would be local to the 'sale' subroutine, but it is visible in the 'refund' subroutine.</p> |

Taking a structured approach is advantageous in several ways:

- All advantages to using subroutines apply here (e.g. working is easier, testing is easier, code is readily reused).
- The code is easier to read, understand and debug.
- Changes can be made to a module within the program without affecting the rest of the program. If one of your subroutines worked, for example, its name and parameters would remain the same, so no changes would need to be made by whoever is calling it.

**COPYRIGHT
PROTECTED**

3.2.11. Robust and Secure Programming

| Robust | |
|--|---|
| A robust program continues to function even when confronted with unexpected events, such as a lost network connection or a user inputting data of the wrong data type. | A secure program prevents altering data that they are not supposed to. Usernames and passwords are kept secure, keeping a program secure. |

Validation – ensuring that data entered into the computer is reasonable. For example, checking that a person's date of birth isn't in the future. Validation does not ensure that the data is correct, only that it is reasonable.

Different types of data can be input, so a range of validation checks exist to suit:

Range check ensures that data is within a specified range, e.g. ensuring a time is between 0 and 30 seconds, or ensuring a person's birthdate is between 1900 and 2020.

```
isValid = True
while isValid == False:
    bedrooms = int(input("How many bedrooms: "))
    if bedrooms >= 1:
        isValid = True
    else:
        print("Please enter a positive number")
```

This code ensures that the user enters a valid number of bedrooms. If the user enters a number less than 1, the rule will state the message.

Type check ensures that the correct data type has been entered (e.g. integer, string, float).

Length Check ensures that a string contains a valid number of characters, e.g. a phone number or national insurance number.

```
isValid = False
while isValid == False:
    name = input("Name: ")
    if len(name) >= 3:
        isValid = True
    else:
        print("Minimum length: 3 characters")
```

This code repeats the loop until the user enters a name with at least 3 characters. Replace the number 3 with the required length.

Lookup check checks that what the user has entered exists on a list, such as a list of weekdays. In a shopping list, the user can select the item from a list of items.

Presence check simply checks that the user has entered something. This ensures that the length is greater than zero.

Authentication – the software process of ensuring that the person accessing the system is who is *supposed* to access that system. The following might be used:

- Usernames and passwords
 - Memorable information – prompting for something only the real user would know, such as a favourite place or the name of a first pet
 - Checking that the user is using their usual computer, by logging the IP address
- Authentication techniques are used throughout the cyber security world.

Selecting Test Data

Choice of test data is important. Suppose you have written a program for an estate agent to calculate the number of bedrooms in a house, which must be an integer between 1 and 15:

| Type of Test Data | Description |
|---------------------------|--|
| Normal (typical) | Data that is valid and that represents how the program would be used. |
| Boundary (extreme) | Data that is just barely valid, to check that the extreme range of normal input work correctly. Also, data that is just barely invalid, to check that invalid data close to it might be to valid data, is correctly rejected. |
| Erroneous | Data that should not be accepted by the system. This is important to check whether a program's validation and error messages work correctly. |

If you have a piece of code that is supposed to sort eight positive integers into ascending order, some of test data each have a specific purpose:

| Test Data | Explanation |
|-------------------|--|
| 1 2 3 4 5 6 7 8 | The data is already sorted, so the program should be checked). |
| 8 7 6 5 4 3 2 1 | The values are in descending order, which is as far from being in ascending order as possible. |
| 2 6 4 3 8 7 5 | How does the program react to having a number that is not in order? |
| -1 2 3 4 5 6 7 8 | How does the program react to having a negative number? |
| 1 2 3 4.2 5 6 7 8 | How does the program react to one piece of data not being an integer? |
| 5 4 4 2 9 8 8 5 | Does the program work correctly if there are duplicate values? |

Errors

Even the most experienced programmers write code with errors. So many errors can be divided into two main types:

Syntax error – the grammar or rules of the language have not been followed, such as 'for' has been misspelled, or perhaps indentation has not been used correctly. A syntax error causes a program to stop working or perhaps not even start.

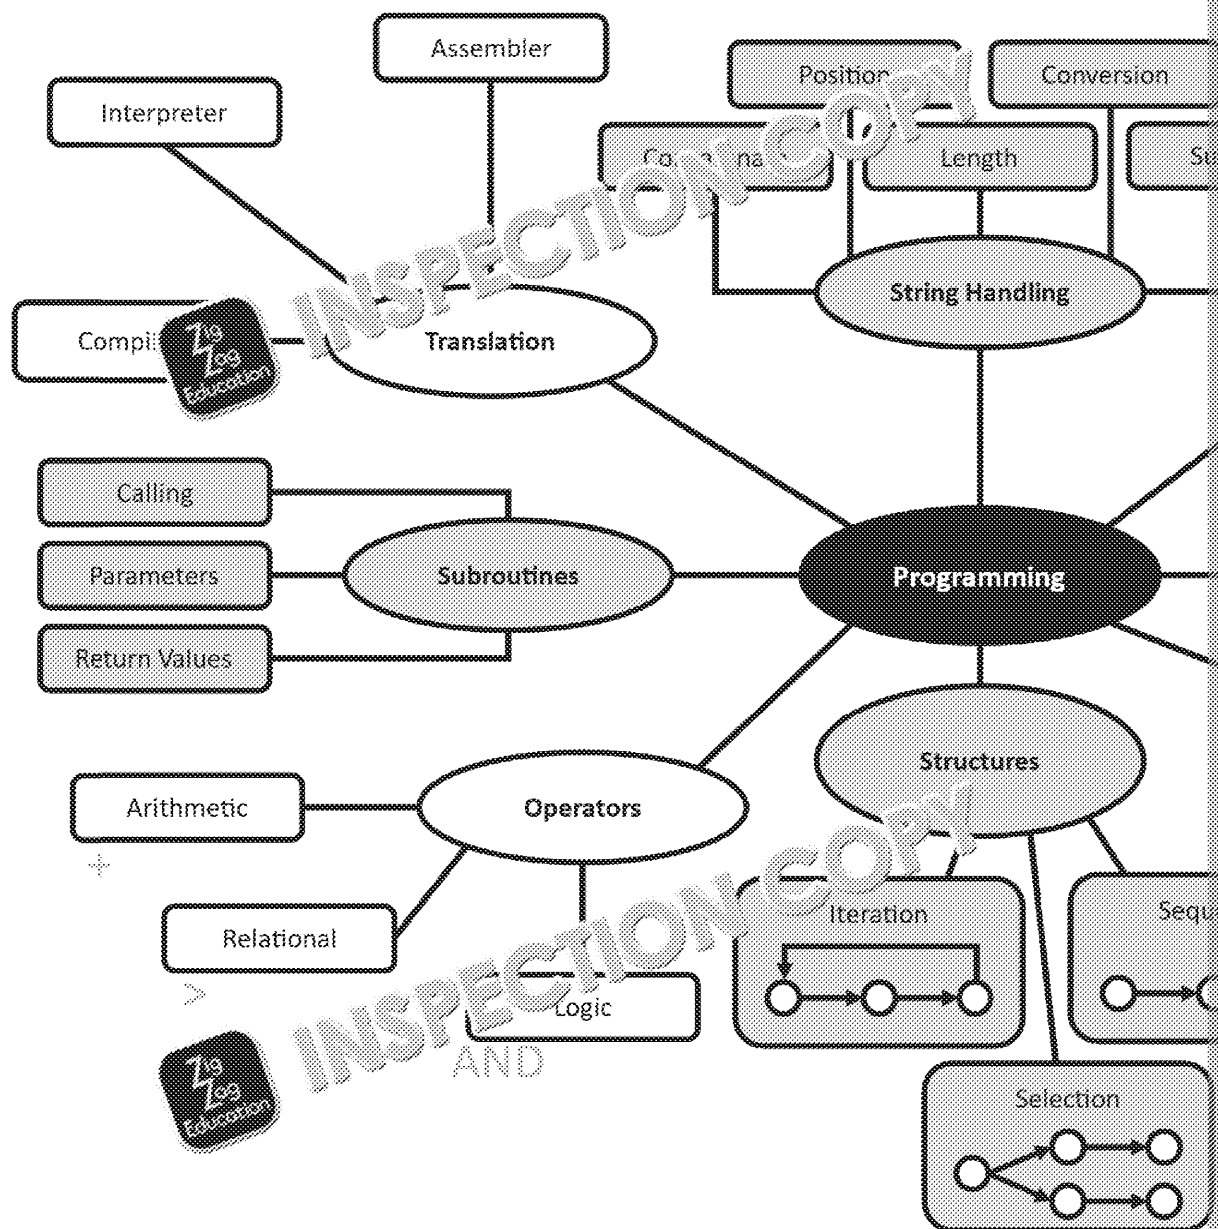

Logic error – a piece of code is written incorrectly in a way that does not do what is intended. The programmer might have added when they meant to subtract, or used 100 instead of 10 for a percentage calculation.

Sample Examination-style Questions

4. This question is based on the following program:

```
total ← 0                #keeps a running total
count ← 0                #logs how many are entered
mean ← 0                 #to store the mean
input ← USERINPUT
WHILE input > -1
    total ← total + input
    count ← count + 1
    input ← USERINPUT
ENDWHILE
mean ← total / count
OUTPUT mean
```

a. Give an example of each of the following from the code:

i. Variable

.....

ii. Comment

.....

iii. Arithmetic operator

.....

iv. Relational operator

.....

v. Iteration keyword

.....

b. When the program is running, what would the user need to do in order to have entered all of their numbers?

.....

5. A bank stores several pieces of data about each bank account. Identify the type of each of the following pieces of data. Some data types are used more than once.

Place **one** tick in each row.

| Data | Integer | Real | Boolean | String |
|---|---------|------|---------|--------|
| Money in account | | | | |
| Account holder's name | | | | |
| Number of whole years the account has been active | | | | |
| Account holder's postal address | | | | |
| Whether or not an overdraft is permitted | | | | |
| A single-letter code that identifies the account type | | | | |

6. An array called `data` contains 10 numbers, each being an integer between 0 and 10. Write an algorithm to copy the values in the array to a new array if the values are higher than 5.

Algorithm:

```

1. Create a new array called newData with size 10.
2. For each index i from 0 to 9:
   a. If data[i] > 5, then
      i. Set newData[i] = data[i]
   b. Otherwise,
      i. Set newData[i] = 0
3. End For

3.3. Fundamentals of Data Representation

3.3.1. Number Bases

Number base – the number of unique digits available in a numbering system. In the **decimal** (the numbering system you're most used to), there are 10 unique digits (0, 1, 2, 3, 4, 5, 6, 7, 8, 9), so it is also known as **base 10**.

| Numbering System | Available Digits |
|-----------------------|---------------------------------|
| Binary (base 2) | 0 1 |
| Decimal (base 10) | 0 1 2 3 4 5 6 7 8 9 |
| Hexadecimal (base 16) | 0 1 2 3 4 5 6 7 8 9 A B C D E F |

Computers can only represent all data and instructions. Whatever a user enters, whether it's text, images, sound or video, it is ultimately stored as a string of '0's and '1's.

Hexadecimal is often used in computer science as a human-readable alternative to binary. One hexadecimal digit is equivalent to four binary digits. The largest single-digit hexadecimal digit is 'F', which translates to 1111 in binary. Consider which of the following is easier for you to type: **A42C** or **1010010000101100**.

They both represent the same value. The hexadecimal value is easier for a human to type, as it is less prone to error when being typed in.

3.3.2. Converting between Number Bases

The largest values you'll be expected to convert in an exam are 255 in decimal, and FF in hexadecimal (all of which are equivalent to each other).

Binary → Decimal

This conversion will use the example binary number 11001010. The first step is to identify the value of each binary digit. The placeholder above the rightmost bit is '1', and the value of each bit doubles as you move to the left:

| | | | | | | | |
|-----|----|----|----|---|---|---|---|
| 128 | 64 | 32 | 16 | 8 | 4 | 2 | 1 |
| 1 | 1 | 0 | 0 | 1 | 0 | 1 | 0 |

Add together the placeholder values that contain a '1':

$$128 + 64 + 8 + 2 = 202$$

**COPYRIGHT
PROTECTED**

Decimal → Binary

The following steps show you how the number **85** is converted, with no need for

| Instruction | Answer so far | | | | | | | | | | | | | | | | |
|--|--|-----|----|----|----|---|--|--|--|---|---|---|---|---|--|--|--|
| We know that there will be eight bits in our answer, so we create a space for eight digits. | <table><tr><td></td><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr></table> | | | | | | | | | | | | | | | | |
| | | | | | | | | | | | | | | | | | |
| We can then write in the value of each digit immediately above. Start with '1' on the right-hand side, then double each time you add a new number to the left. | <table><tr><td>128</td><td>64</td><td>32</td><td>16</td><td>8</td><td></td><td></td><td></td></tr><tr><td></td><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr></table> | 128 | 64 | 32 | 16 | 8 | | | | | | | | | | | |
| 128 | 64 | 32 | 16 | 8 | | | | | | | | | | | | | |
| | | | | | | | | | | | | | | | | | |
| Now, we start with the left-most bit. 128 is higher than the number we're trying to convert, so we enter a '0'. | <table><tr><td>128</td><td>64</td><td>32</td><td>16</td><td>8</td><td></td><td></td><td></td></tr><tr><td>0</td><td></td><td></td><td></td><td></td><td></td><td></td><td></td></tr></table> | 128 | 64 | 32 | 16 | 8 | | | | 0 | | | | | | | |
| 128 | 64 | 32 | 16 | 8 | | | | | | | | | | | | | |
| 0 | | | | | | | | | | | | | | | | | |
| Next, we look at 64, which is smaller than the number we're trying to convert, so we enter a '1' and subtract 64 from our number. | <table><tr><td>128</td><td>64</td><td>32</td><td>16</td><td>8</td><td></td><td></td><td></td></tr><tr><td>0</td><td>1</td><td></td><td></td><td></td><td></td><td></td><td></td></tr></table> | 128 | 64 | 32 | 16 | 8 | | | | 0 | 1 | | | | | | |
| 128 | 64 | 32 | 16 | 8 | | | | | | | | | | | | | |
| 0 | 1 | | | | | | | | | | | | | | | | |
| The next number is 32, which is bigger than the number we're trying to convert (21 at this point, as we've subtracted 64 in our last step). We enter '0' and leave our number unchanged. | <table><tr><td>128</td><td>64</td><td>32</td><td>16</td><td>8</td><td></td><td></td><td></td></tr><tr><td>0</td><td>1</td><td>0</td><td></td><td></td><td></td><td></td><td></td></tr></table> | 128 | 64 | 32 | 16 | 8 | | | | 0 | 1 | 0 | | | | | |
| 128 | 64 | 32 | 16 | 8 | | | | | | | | | | | | | |
| 0 | 1 | 0 | | | | | | | | | | | | | | | |
| Our number (21) is larger than the next digit (16), so we enter a '1' and subtract 16. | <table><tr><td>128</td><td>64</td><td>32</td><td>16</td><td>8</td><td></td><td></td><td></td></tr><tr><td>0</td><td>1</td><td>0</td><td>1</td><td></td><td></td><td></td><td></td></tr></table> | 128 | 64 | 32 | 16 | 8 | | | | 0 | 1 | 0 | 1 | | | | |
| 128 | 64 | 32 | 16 | 8 | | | | | | | | | | | | | |
| 0 | 1 | 0 | 1 | | | | | | | | | | | | | | |
| With only 5 left to convert, which will clearly be made up of a '1' and a '4', we place '1's into each of these columns and '0's into the others. | <table><tr><td>128</td><td>64</td><td>32</td><td>16</td><td>8</td><td></td><td></td><td></td></tr><tr><td>0</td><td>1</td><td>0</td><td>1</td><td>0</td><td></td><td></td><td></td></tr></table> | 128 | 64 | 32 | 16 | 8 | | | | 0 | 1 | 0 | 1 | 0 | | | |
| 128 | 64 | 32 | 16 | 8 | | | | | | | | | | | | | |
| 0 | 1 | 0 | 1 | 0 | | | | | | | | | | | | | |

The binary equivalent of '85' is '01010101'.

The right-most binary digit is always '1', then '2', '4', '8', etc., doubling each time. As the binary number varies from eight bits, the left-most bit will change, but the right-most will always be '1'.

This topic is quite an easy one to practise without any past paper questions. Try converting a number between 0 and 255, or use a random number generator. Convert it to binary, then check that you end up with the same number with which you started.

This technique also applies to example questions, if you have time. If you've been asked to convert a number from binary to decimal, you can check it by converting your answer back to binary. You should arrive back at the original number in the question.

**COPYRIGHT
PROTECTED**

Hexadecimal → Decimal

The table below shows all single-digit hexadecimal values, along with their binary

| Binary Representation | Decimal Representation |
|-----------------------|------------------------|
| 0000 | 0 |
| 0001 | 1 |
| 0010 | 2 |
| 0011 | 3 |
| 0100 | 4 |
| 0101 | 5 |
| 0110 | 6 |
| 0111 | 7 |
| 1000 | 8 |
| 1001 | 9 |
| 1010 | 10 |
| 1011 | 11 |
| 1100 | 12 |
| 1101 | 13 |
| 1110 | 14 |
| 1111 | 15 |

Binary → Hexadecimal

1. This is a binary number we will convert to hexadecimal.
2. If the binary number has a number of digits divisible by four (4-digit, 8-digit, 12-digit, etc.), it can be left alone. Otherwise, add '0's to the left until you have such a number. Since our number has six digits, we will add two '0's to the left of it.
3. Next, split the number into 'nibbles' of four bytes each.
4. Finally, convert each nibble separately, using the table above. This table contains every possible value for a binary nibble.

So '011110' in binary is equivalent to '1E' in hexadecimal.

Hexadecimal → Binary

5. This is the hexadecimal number we will convert to binary.
6. Each hexadecimal digit will translate to a binary nibble, according to the table above. Translate each digit separately.
7. Attach the nibbles together. If you choose to, you may leave a space between them for readability, but you do not have to.

So 'A6' in hexadecimal is equivalent to '10100110'.

If you need to convert between decimal and hexadecimal numbers, the best way is to use a binary number, so either **decimal → binary → hexadecimal** or **hexadecimal → binary → decimal** depending on the conversion you are asked to make.

PROTECTED**

3.3.3. Units of Information

| Unit Name | Size | |
|---------------|--|---|
| Bit (b) | A single <u>binary</u> digit. | Either a 0 or 1 |
| Byte (B) | A sequence of eight bits. | An individual character, such as 'a' or '1' |
| Kilobyte (KB) | Approximately 1,000 bytes. | A paragraph of text, or about 200 words |
| Megabyte (MB) | Approximately 1,000 kilobytes or 1,000,000 (one million) bytes. | Around 10 minutes of mp3 music |
| Gigabyte (GB) | Approximately 1,000 megabytes or 1,000,000,000 (one billion) bytes. | About 100 minutes of HD video, or a few months of email |
| Terabyte (TB) | Approximately 1,000 gigabytes or 1,000,000,000,000 (one trillion) bytes. | Depends on how much you use it, but could be hundreds of years of email |

Historically, the kilobyte measure was sometimes considered to be 1,024 times larger than the byte measure, and the megabyte was often considered to be 1,024 kilobytes, rather than 1,000. This is because 2^{10} is 1,024.

However, all other measurements with a mega- prefix (such as megawatt, megajoule, or megagram) are exactly 1,000 times their corresponding kilo-prefixed measurements (kilowatt, kilojoule, and kilogram), and it's now understood that one megabyte is 1,000 kilobytes.

Your teacher may disagree, and isn't necessarily wrong (it's a bit like the argument about the pronunciation of 'gif'), but the AQA specification stipulates multiples of 1,000, not 1,024.

Be aware of the difference between the shorthand form for bits (lower case 'b') and bytes (upper case 'B'). If you look at your home broadband speed, it is probably measured in megabits per second (Mbps), not MBps (megabytes per second).

3.3.4. Binary Arithmetic

You need to be able to add up to three binary numbers together as well as to perform other operations like shifting.

Binary shift – moving (shifting) the values of a binary number left or right.

a. 00011000 → Shift right by one place → 00001100

b. 00001100 → Shift left by two places → 00110000

When you shift left or right, any bits that fall off the end are lost forever; any bits that fall off the other end are *always* '0':

| Shift | Operation | Result |
|----------------|---------------|--------|
| Shift 1 place | Multiply by 2 | |
| Shift 2 places | Multiply by 4 | |
| Shift 3 places | Multiply by 8 | |

Addition of numbers in binary is similar to addition of numbers in decimal. The numbers are added one by one, and each pair is added, going from right to left. In binary, when adding two 1s, there are only five possible combinations of numbers, because we're only dealing with '1's and '0's:

- 0 + 0 = 0
- 0 + 1 = 1
- 1 + 0 = 1
- 1 + 1 = 10 (seems strange, but '10' is binary for '2')
- 1 + 1 + 1 = 11 ('11' is binary for '3', and you will only need this one for carrying)

COPYRIGHT
PROTECTED

Binary Addition Walkthrough

1. The two numbers to be added are stacked one on top of the other.
2. Starting from the right-most digits, the first pair is added together. $1 + 0 = 1$.
3. The next pair is just as straightforward: $0 + 0 = 0$.
4. As for the next pair, $1 + 1 = 2$, which is 10 in binary. Just as in adding decimal numbers, we carry the '1' and place the '0' in the answer.
5. Next, we add $0 + 1 + 1$ (the carried '1'). In binary, $0 + 1 + 1 = 10$, so another '0' and another carried '1'.
6. Here, it's $1 + 1 + 1$ including the carried digit. In binary, $1 + 1 + 1 = 11$.
7. Again, $1 + 1 + 1 = 11$.
8. Now, $0 + 0 + 1$ (the carried '1') gives us '1'.
9. The final pair on the left is $1 + 0 = 1$.

When adding together three numbers, if you can't perform the addition in a single step, add the first two together, then add the third to the result. In the exam, you should convert the numbers to decimal, then add, then convert back to binary. This is likely to lose you marks.

PROTECTED**

3.3.5. Character Encoding

Character – a single symbol, such as a letter, number, symbol or space cause one character to appear on the screen.

Character set – a list of all characters recognised by a computer system corresponding code, and the same codes are used by all computers that use the **ASCII** (American Standard Code for Information Interchange) and **Unicode** character sets.

| Character Value | ASCII | Unicode |
|-----------------|-----------|---------|
| A | 0100 0001 | |
| a | 0110 0001 | |
| 0 | 0010 0011 | |
| 1 | 0011 0011 | |

Characters are commonly grouped and run in the order that you would expect, 'A' is 65, 'B' is 66, 'C' is 67, 'D' is 68, etc. In lower case, 'a' is 97, etc. Numerals (0, 1, 2, 3, etc.) are similarly grouped together.

ASCII uses seven bits, meaning 128 different characters (2^7) can be represented.

Unicode uses sixteen bits, meaning 65,536 different characters (2^{16}) can be represented. Unicode gives you access to far more alphabets, including Chinese, Japanese, and many more, but more storage space is required.

ASCII and Unicode use the same codes for characters up to code 127 (1111 1111). For example, 'A' is 100 0001 in ASCII and 0000 0000 0100 0001 in Unicode.

3.3.6. Representing Images

One way to store images is to divide them into pixels, each of which is a tiny dot that can be one colour, and when a picture is saved, the colour of each individual pixel is stored. The more pixels that are used to store each pixel, the more colours are potentially available.

Pixel – short for *picture element*, this term refers to the smallest possible unit of an image on a screen. A pixel cannot be divided up into smaller units, and a pixel can only have one colour at a time.

```
1 1 1 0 0 1 1 1
1 1 0 0 0 0 1 1
1 0 0 0 0 0 0 1
0 0 1 0 0 1 0 0
0 0 0 0 0 0 0 0
1 1 0 1 1 0 1 1
1 0 1 0 0 1 0 1
0 1 0 1 1 0 1 0
```

When working with **monochrome** images, each pixel is either on or off, so one bit can represent one pixel.

The image above is eight pixels by eight, so 64 pixels in total. Only black and white are enough to represent each pixel, set to '0' for black or '1' for white. This means 64 bits are enough to store the data for the pixels of this image.

If more colours are needed, more bits are needed. Many images store 24 bits, three bytes, in this way:

| First byte | Second byte | |
|------------|-------------|--|
| 11111111 | 10001011 | |
| Red | Green | |

The 'red' value in the first byte is as high as it can be, so there will be lots of red in the image. There will be some green, but not as much as red, and there will be no blue at all as the third byte is all zeros. Over 16 million colours are available, but a 64-pixel image saved in this format will take up 1,536 bytes of storage, compared with eight for the image above.

The amount of storage required for an image depends on a number of factors, including:

- **Colour depth** – a measure of how many colours are available; the more colours, the more bits that must be assigned to store each pixel.
- **Image size** – the number of pixels in *height* and *width* for an image, often referred to as resolution. A higher-resolution image (i.e. more pixels) requires more storage space than a lower-resolution image.

Calculating an Image File Size

| | |
|----------|---|
| W | The width of an image, measured in pixels |
| H | The height of an image, measured in pixels |
| D | The colour depth; the number of bits used to store each pixel |

File size in **bits**: $W \times H \times D$
 File size in **bytes**: $(W \times H \times D) / 8$

To convert file size from **bytes** to **kilobytes**, divide the number of bytes by 1,000.
 To convert file size from **bytes** to **megabytes**, divide the number of bytes by 1,000,000.

COPYRIGHT
PROTECTED

3.3.7. Representing Sound

Sound is analogue, and must be converted to digital before it can be stored or processed.

Analogue – sound is an analogue signal, which is the opposite of digital. With digital signals, processing '0's and '1's – nothing else, nothing in between. Analogue is continuously variable. It might be one of two values, such as '0' or '1' or '0.1879'. Sound is an analogue signal, since frequencies do not occur in discrete steps.

Analogue data needs to be converted to digital in order to be stored and processed. This is done by taking **samples** of the sound's **amplitude**. With sound, thousands of samples are taken per second. Each sample is a measure of the amplitude at a specific point in time:

(each dotted line represents a sample)

Sampling rate – a measure of how often a sample is taken, measured per second. 1 MHz (megahertz) means one million times per second. Higher sampling frequency:

A higher sampling rate results in higher accuracy but requires more storage space. The sampling rate is measured in samples per second of audio.

Sample resolution – not to be confused with screen resolution, which is measured in *pixels*. Resolution in sound sampling refers to how many bits are required to store each sample. More bits means better quality, but also more storage space.

Calculating Sound File Size

| | |
|-------------|--|
| Rate | Sampling rate – the number of samples per second |
| Res | Sample resolution – the number of bits used to store each sample |
| Secs | Seconds – the length, in seconds, of the whole sound file |

File size in **bits**: $\text{Rate} \times \text{Res} \times \text{Secs}$
 File size in **bytes**: $(\text{Rate} \times \text{Res} \times \text{Secs}) / 8$

COPYRIGHT
PROTECTED

3.3.8. Data Compression

Compression – techniques to reduce the size of a file, so that it takes less time to be transmitted across a network more quickly. There are many different techniques, but only a small subset of which are covered at GCSE level.

Huffman Encoding

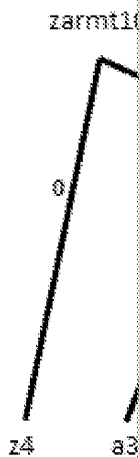

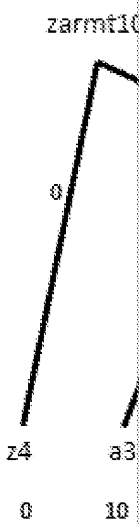

Huffman encoding – a form of lossless compression that represents characters with smaller bit patterns, and rarely used characters with larger bit patterns.

| | |
|--|--|
| Begin with the text, which would, in most cases, be more than a single word. | r |
| Identify all the letters. | r |
| Count how often each letter appears. | r 1 |
| At the bottom of your page, write down the letters in descending order of how often they appear. | z 4 |
| Create a V linking the two lowest-frequency letters, and write the combination of the letters, and their total frequency, at the peak of the 'V'. | z4 a3 |
| Repeat the process, this time remembering that 'mt2' is now a possible option and that 'm1' and 't1' are not. | z4 a3 |
| Continue until all letters have a path, however long, to the top of the tree. | <div> <div>zarmt16</div> <div> <div>z4</div> <div>a3</div> </div> </div> |

COPYRIGHT
PROTECTED

| | |
|---|---|
| <p>Label each left branch with a '0' and each right branch with a '1'.</p> |  |
| <p>Give each letter a binary code made up of all the '1's and '0's encountered, in order, from the top of the tree.</p> |  |

This is a **Huffman Tree**

To write 'razzmatazz', using this encoding, the following bit strings would be used

110 10 0 0 1110 10 1111 10 0 0

In fact, the spaces can be removed, since there is no way one code could be mistaken for another.

110100011101011111000

An ASCII representation of the word 'razzmatazz' would have required 70 bits (10 characters multiplied by seven bits per character). The Huffman encoded representation, however, requires only 21 bits. This is because the most commonly used character, 'z', is assigned the shortest code, '0'. Of course, some of this saving would be lost due to the fact that the Huffman tree itself would also have to be transmitted. However, for larger amounts of text, a substantial saving can be made in terms of file size, even when the size of the Huffman tree is factored in.

**COPYRIGHT
PROTECTED**

Run Length Encoding (RLE)

Run length encoding – a form of compression that is effective when data is repeated. Instead of storing each item of repeated data, the data is stored once and the number of times it repeats.

A run length encoding algorithm is a straightforward means of lossless compression for storing or transmitting a file that contained lots of repeated data, such as:

- A text file that contains repeated characters, e.g. 'zzzzzzzzzzzzzz'
- An image file where lots of adjacent pixels are an identical colour
- A sound file containing stretches of complete silence

If we consider a bit pattern, which could represent a sound, image, or any other form of data, it might operate in the following way:

Uncompressed: 111110000000111100000000111111111
Compressed: 5 1 6 0 4 1 8 0 9 1

Each block of one symbol (1 or 0) is now reduced to that symbol, once, alongside the number of many consecutive instances exist. The first five '1's have been replaced by a 5 (the number of times). This would not work for every file you attempt to compress:

Uncompressed: QWERTY
Compressed: 1Q1W1E1R1T1Y

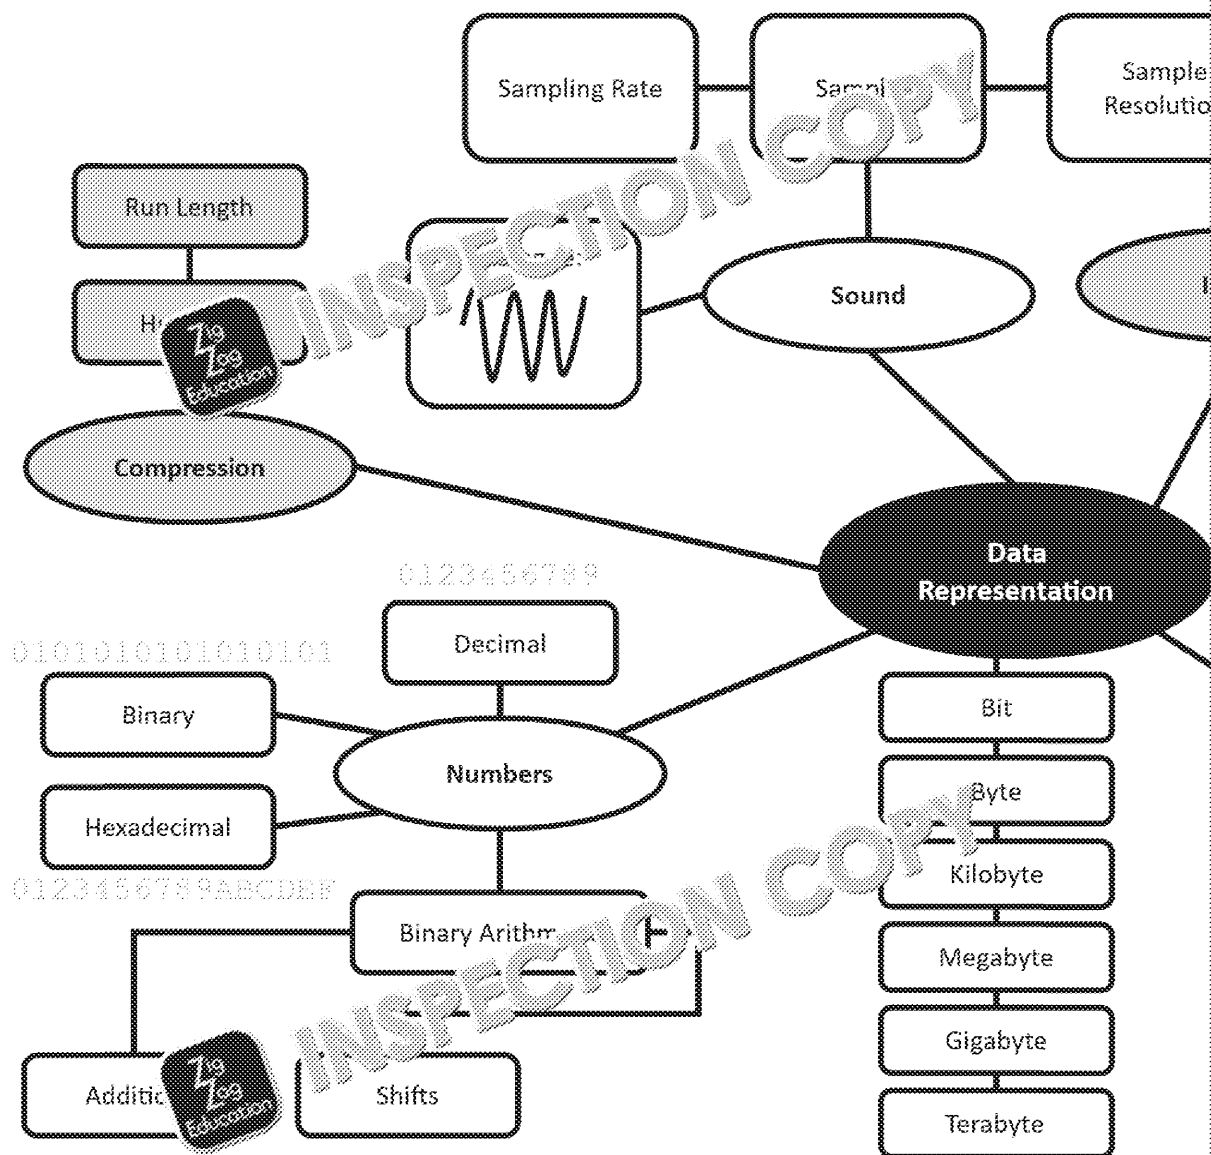

Because no letters were repeated in the uncompressed file, the 'compression' produces a larger file.

3.4. Computer Systems

3.4.1. Hardware and Software

Hardware – the physical components that make up a computer system, including memory, storage, and input and output devices.

Software – the programs that run on a computer, including operating systems and application software (which includes mobile apps).

The role of software, ultimately, is to tell hardware how to behave – what to do. Without software, hardware is of no use from a computer science standpoint.

3.4.2. Boolean Logic

Logic – in computer science, 'logic' refers to producing **Boolean** outputs from combinations of Boolean inputs.

| Logic expression | Gate | Truth table (see symbols) | | | | | | | | | | | | | | | |
|---|--------|---|---|--------|--------|---|---|---|---|---|---|---|---|---|---|---|---|
| AND all inputs must be '1' for the output to be '1' | | <table><tr><th>A</th><th>B</th><th>Output</th></tr><tr><td>0</td><td>0</td><td>0</td></tr><tr><td>0</td><td>1</td><td>0</td></tr><tr><td>1</td><td>0</td><td>0</td></tr><tr><td>1</td><td>1</td><td>1</td></tr></table> | A | B | Output | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | 1 | 1 |
| A | B | Output | | | | | | | | | | | | | | | |
| 0 | 0 | 0 | | | | | | | | | | | | | | | |
| 0 | 1 | 0 | | | | | | | | | | | | | | | |
| 1 | 0 | 0 | | | | | | | | | | | | | | | |
| 1 | 1 | 1 | | | | | | | | | | | | | | | |
| OR if either input, or both inputs, is '1', the output is '1' | | <table><tr><th>A</th><th>B</th><th>Output</th></tr><tr><td>0</td><td>0</td><td>0</td></tr><tr><td>0</td><td>1</td><td>1</td></tr><tr><td>1</td><td>0</td><td>1</td></tr><tr><td>1</td><td>1</td><td>1</td></tr></table> | A | B | Output | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | 1 | 1 | 1 | 1 |
| A | B | Output | | | | | | | | | | | | | | | |
| 0 | 0 | 0 | | | | | | | | | | | | | | | |

A truth table can be more complex. If we consider an automated greenhouse, we have an automatic sprinkler (water = 1) only if the soil is dry (moisture = 0), it is daytime (light = 1) and the door is closed (door = 0). In all other events, the sprinkler is turned off (water = 0).

| Inputs | | | Output |
|----------------------|-------------------|------------------|-------------------|
| Moisture <i>M</i> | Light <i>L</i> | Door <i>D</i> | Water <i>W</i> |
| 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 0 |
| 0 | 1 | 0 | 1 |
| 0 | 1 | 1 | 0 |
| 1 | 0 | 0 | 0 |
| 1 | 0 | 1 | 0 |
| 1 | 1 | 0 | 0 |
| 1 | 1 | 1 | 0 |

One possible logic circuit for this truth table would be as follows:

This logic circuit could also be written as a Boolean expression:

$$W = \bar{M} \cdot L \cdot \bar{D} \text{ (water = (NOT moisture) AND light AND (NOT door))}$$

3.4.3. Software Classification

COPYRIGHT
PROTECTED

System software – programs that are needed for effective communication between the user and the computer. Examples include:

- Operating system, such as Windows and Android
- Utility software, such as antivirus and compression software

Application software – programs launched from the operating system to perform a specific task or group of tasks. Examples include:

- Desktop applications such as browsers and word processing packages
- Mobile apps

The Operating System

Operating system – a piece of system software that acts as an interface between hardware, managing all hardware and all other software. If another program is launched, it will be launched from the operating system.

Operating systems are complex pieces of software, often requiring many years to develop them. The reason that they are complex is simply that computers are complex, and software that requires management. Among many things managed by the operating system are:

| | |
|---------------------|--|
| Processor(s) | <p>The operating system decides...</p> <ul style="list-style-type: none"> Which processes will be carried out, and which processors If multiple processes are running, which one the processor should work on How long a time slice each process should be given, i.e. how long the processor's attention switches to the next process |
| Memory | <p>The operating system...</p> <ul style="list-style-type: none"> Loads programs and data from backing store to main memory Removes unneeded programs and data to make room for other programs Manages virtual memory where part of secondary storage is used as an extension for main memory. |
| I/O devices | <p>Regarding input/output devices, the operating system...</p> <ul style="list-style-type: none"> Acts as a go-between, passing data from input → application software → output Manages device drivers, which are programs telling the operating system how to communicate with attached input/output devices |
| Applications | <p>The operating system...</p> <ul style="list-style-type: none"> Communicates between application software and hardware Processes requests from application software for resources, such as a connection or a remotely stored file |
| Security | <p>The operating system can...</p> <ul style="list-style-type: none"> Manage multiple user accounts, keeping users' data separate Automatically back up data, thereby increasing its security Handle usernames and passwords to prevent unauthorised access Recognise one user as an administrator, who would have special permissions |

Utility software – programs that keep the computer functioning efficiently, such as freeing storage space, removing viruses or ensuring the files are backed up.

| Utility | Purpose |
|------------------------|---|
| Compression | Reducing the size of a file so that it can be stored using less space and is more quickly transferred. |
| Defragmentation | Moving separate parts of a file physically together, to speed up access. |
| Backing up | <p>Creating a copy of files, either on the same disk, on a backup device or on a network.</p> <p>Backing up can be either full or incremental:</p> <ul style="list-style-type: none"> Full backup involves creating a copy of all files Incremental backup involves creating a copy only of files that have been edited since the last backup |
| Encryption | Allowing for data to be scrambled in order to prevent unauthorised users from understanding any files that they see. This might be for security or privacy. |

INSPECTION COPY

COPYRIGHT
PROTECTED

3.4.4. Classification of Programming Languages and Translators

| | High-level | Low-level |
|--|---|--|
| What is it? | High-level languages are more understandable to humans than low-level language, so high-level languages are far more popular | More difficult to write and be executed |
| Examples | <ul style="list-style-type: none"> • Java • Visual Basic • Python • C# | <ul style="list-style-type: none"> • Machine code (1s and 0s) • Assembly language (more readable than machine code, but still makes no sense like ADD, MOV, etc. as a clue as to what it does) |
| What do you need in order to run code written in these languages? | Either an interpreter or a compiler to enable the code that is typed to be translated into machine code so that the computer can run it. | Machine code can be run directly - it is the language the computer understands |
| What does code look like? | <p>One line of code might do <i>several</i> things, e.g.:</p> <pre>A = B + C</pre> <p>This instruction finds out the values of B and C, adds them together, then stores the result in B.</p> <p>As one line of code can do several things, one line of a high-level language often translates into several lines of machine code.</p> | <p>One line of code in assembly language does one task</p> <pre>LDA B ADD C STA A</pre> <p>These instructions do one task as $A = B + C$. Most people find assembly code and machine code unintelligible.</p> |
| Suitability | <ul style="list-style-type: none"> • More appropriate if the program is to be used on a variety of different computer builds • Far more people are proficient in high-level than low-level languages, so this may dictate the language type used | <ul style="list-style-type: none"> • Likely to be used in systems where space and location are at a premium and need to be addressed precisely • Suited to embedded systems where execution speed is important |

Machine code is **machine specific**, meaning a machine code program written for one computer will not necessarily work on another. This is because different computers sometimes have different internal layouts and components, which can affect the way that machine code is executed.

INSPECTION COPY

COPYRIGHT
PROTECTED

Translator – a program that translates **source code** (which is written in a high-level language) into **machine code** (which can be executed by the computer). There are three types of translators:

- **Assemblers** translate assembly language
- **Interpreters** translate then execute high-level code, one line at a time
- **Compilers** translate an entire high-level program before executing it

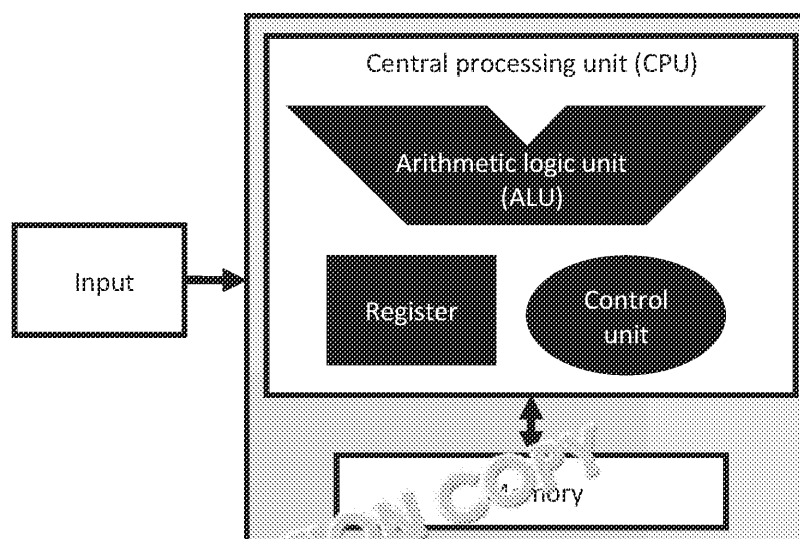

Computers can only execute machine code. If a program is written in a high-level language, it must be translated to machine code before it can be executed.

For low-level translation, an assembler is the right tool for the job. For high-level translation, both interpreters and compilers each have advantages and disadvantages.

| Interpreter | |
|---|---|
| + A program that contains errors will be run, up to where the error occurs | + A compiled object code file is faster than reinterpreting the source code |
| + Debugging is easier as the problematic line can be more easily pinpointed | + It is more difficult to modify a compiled program |
| - Every time you run the program, it needs to be interpreted, which is time-consuming | - More memory is needed to store the entire program than for a compiled program |
| - It is easier for unauthorised people to access your source code | - The entire program must be loaded into memory in order for it to compile |

3.4.5. Systems Architecture

The CPU is connected to other components, and the **von Neumann architecture** describes how the CPU and other parts are connected:

Data is input, processed by the CPU, which has several components of its own, and the result is output. The CPU is also connected to memory, allowing data to be stored. The arrows in this diagram indicate **buses**, which are communication channels that carry data between components.

This model defines the behaviour of many computers. The most advanced game console (or several), an input in the form of a keyboard and mouse, an output in the form of a display and speakers, and vast memory to store the state of the game. A digital alarm clock is also a computer, has an input (the user can set the alarm), outputs (the current time, alarm sound), processing (keeping track of what time it is) and memory (it needs to store the time of the alarm).

COPYRIGHT
PROTECTED

CPU – the central processing unit executes program instructions, performs comparisons, as well as coordinating the behaviour of other hardware components.

| Component | Function |
|---|--|
| Arithmetic Logic Unit (ALU) | <p>Performs various operations:</p> <ul style="list-style-type: none"> • Arithmetic operations (+ - * /) • Relational operations (< > =) • Logic operations (AND, NOT, OR). |
| Control Unit (CU) | Manages the execution of instructions by coordinating other hardware. |
| Buses (collections of wires that transmit data between computer components) | <p>Data bus – moves data back and forth between the CPU and memory.</p> <p>Address bus – transmits memory locations. Any data in memory belongs in a specific address or memory location.</p> <p>Control bus – transmits commands to other components (e.g. READ (get data from memory) or WRITE (put data in memory)).</p> |
| Registers | Short-term storage for small, specific pieces of data, where a register would store data just retrieved from memory or the memory location from which that data came. |
| Clock | Every action performed by the CPU must begin during a clock cycle. The clock generates a pulse billions of times each second (in modern CPUs). |

CPU performance – a CPU with a higher rate of performance can execute instructions faster than a CPU with a lower rate of performance. Several factors can affect CPU performance:

- Number of cores
- Clock speed
- Size of cache

**COPYRIGHT
PROTECTED**

Core – a single unit, comprising an ALU and a Control Unit, which can execute instructions. More cores can execute instructions at the same time, so more cores mean that more instructions can be executed.

Four instructions with one core:

Four instructions with two cores (a **dual core** processor):

Four instructions with four cores (a **quad core** processor):

A dual core processor is not quite twice as fast as a single core processor because of the time taken to organise which core will follow which instructions (this time is called the **overhead**). This overhead is usually small enough that a dual core processor can be considered twice as fast as a single core processor at the same clock speed. It should be noted, however, that not all applications are designed to take full advantage of multiple cores.

Clock speed – the number of clock pulses per second, typically measured in GHz. A processor has a clock that pulses three billion times per second, meaning there are three billion opportunities, each second, for an instruction to begin. Note that instructions usually take more than a single clock pulse to complete.

Cache – stores copies of data or instructions from RAM (defined below) so they can be accessed more regularly. This means that these instructions can be accessed more quickly than if they had to be fetched from RAM each time.

**COPYRIGHT
PROTECTED**

The Fetch-Execute Cycle

Fetch-execute cycle – a continual sequence of tasks that results in instructions being fetched from main memory, *decoded* so that the CPU knows what to do with them, and then *executed* and sent back out. This cycle happens many millions of times per second in a computer.

Fetch

1. The clock pulses. On a 3 GHz processor, this would happen three billion times per second. The CPU can only begin a task as the clock pulses, although a task may take more than one pulse.
2. One of the registers contains the location (in memory) where the next instruction is usually called the '**program counter**'.
3. This location, also called an 'address', is transmitted to memory. The instruction at that address is transmitted along the control bus.
4. Memory responds by sending the content of that address along the data bus. In this case, an instruction is being transmitted, and it is stored in a register called the '**instruction register**'.

Decode

5. The instruction is read by the control unit, which prepares the registers for what is to be done; storing; the nature of this preparation depends on what the instruction was.

Execute

6. Here, the instruction is carried out. It might be one of the following:
 - Retrieve a piece of data from memory and store it in a register
 - Perform some operation on data that is already in a register; if this is an arithmetic operation, the ALU will carry out this part of the task
 - Store something currently in a register, perhaps that has been processed
7. The program counter, which indicates the location of the next instruction, is updated to the location of the instruction that has been executed. *Now, the entire cycle begins again.*

The terms 'fetch-execute cycle' and 'fetch-decode-execute cycle' refer to the same process, with the latter being more precise as it includes a 'decode' phase, whichever term is used.

Memory – a generic term which, when applied to computers, refers to the storage of data and instructions (including instructions) in immediate use. There are several types with different characteristics.

| Term | Definition |
|---------------------|--|
| RAM | Random Access Memory. When a program is loaded from a computer disk, the instructions are loaded into RAM, which is generally much smaller than the disk. When a computer is turned off or subject to a loss of power, the data in RAM is lost. This means that RAM is volatile . If a computer has more RAM, it will be able to run more applications at the same time. |
| ROM | Read Only Memory. 'Read Only' means that the content cannot be changed (it is not volatile). As such, ROM stores data or instructions that will not change. It will typically store bootstrapping instructions, which tell the computer what to do and initialising the operating system when the computer is turned on. |
| Cache Memory | Cache memory stores copies of data or instructions from RAM that are currently being used. This means that these data or instructions can be accessed very quickly. Cache memory will usually be very small, measured in kilobytes or megabytes (see 'Data Representation'). |

**COPYRIGHT
PROTECTED**

| Term | Definition |
|-----------------|---|
| Register | Short-term storage for small, specific pieces of data, within the CPU. It stores data just retrieved from memory; another would store the data that data came from. |

Secondary storage – long-term storage in a computer system, necessary because primary storage is volatile (loses its contents when powered down) and will also run out. Examples of backing store are **optical**, **magnetic** and **solid state**. All of these devices store numbers of '1's and '0's, but they do so in different ways.

| Device | How it works |
|--------------------|---|
| Optical | Ones and zeros are stored and read using lasers. At many points on the surface, it might be smooth, or there might be a pit (a tiny hole). There are different capacities, and some of each type (but not all). CD: Approximately 700 MB, although there is some variation. DVD: 4.7 GB Blu-Ray: 50 GB |
| Magnetic | The surface of a magnetic disk comprises billions or trillions (or more) of tiny areas, each either magnetised or not. A read-write head can read or change them, but magnetic disks need to spin to the correct location, which takes time. |
| Solid state | Solid state storage devices (of which flash drives are one type) have no moving parts, to store data electronically. With no moving parts, they are sturdier and quieter than magnetic or optical devices. With Flash memory, each bit is stored using two transistors. One either holds a charge or does not (0 or 1). You can read the state of the first. |

Cloud storage – this involves storage on remote computers, usually managed by a third party. When a file is saved or loaded, it is transmitted across the Internet, and files often exist around the world. Cloud storage uses magnetic and, increasingly, solid state storage.

| | |
|--|--|
| <ul style="list-style-type: none"> + With data stored remotely, and usually in multiple physical locations, it is less likely to be damaged by fire, etc. or misplaced + Capacity on your local machine is freed up, granting you more storage space | <ul style="list-style-type: none"> - Cloud storage often costs more - The speed at which you can access data is limited by your Internet connection and the time it takes for data to travel days to access a large file |
|--|--|

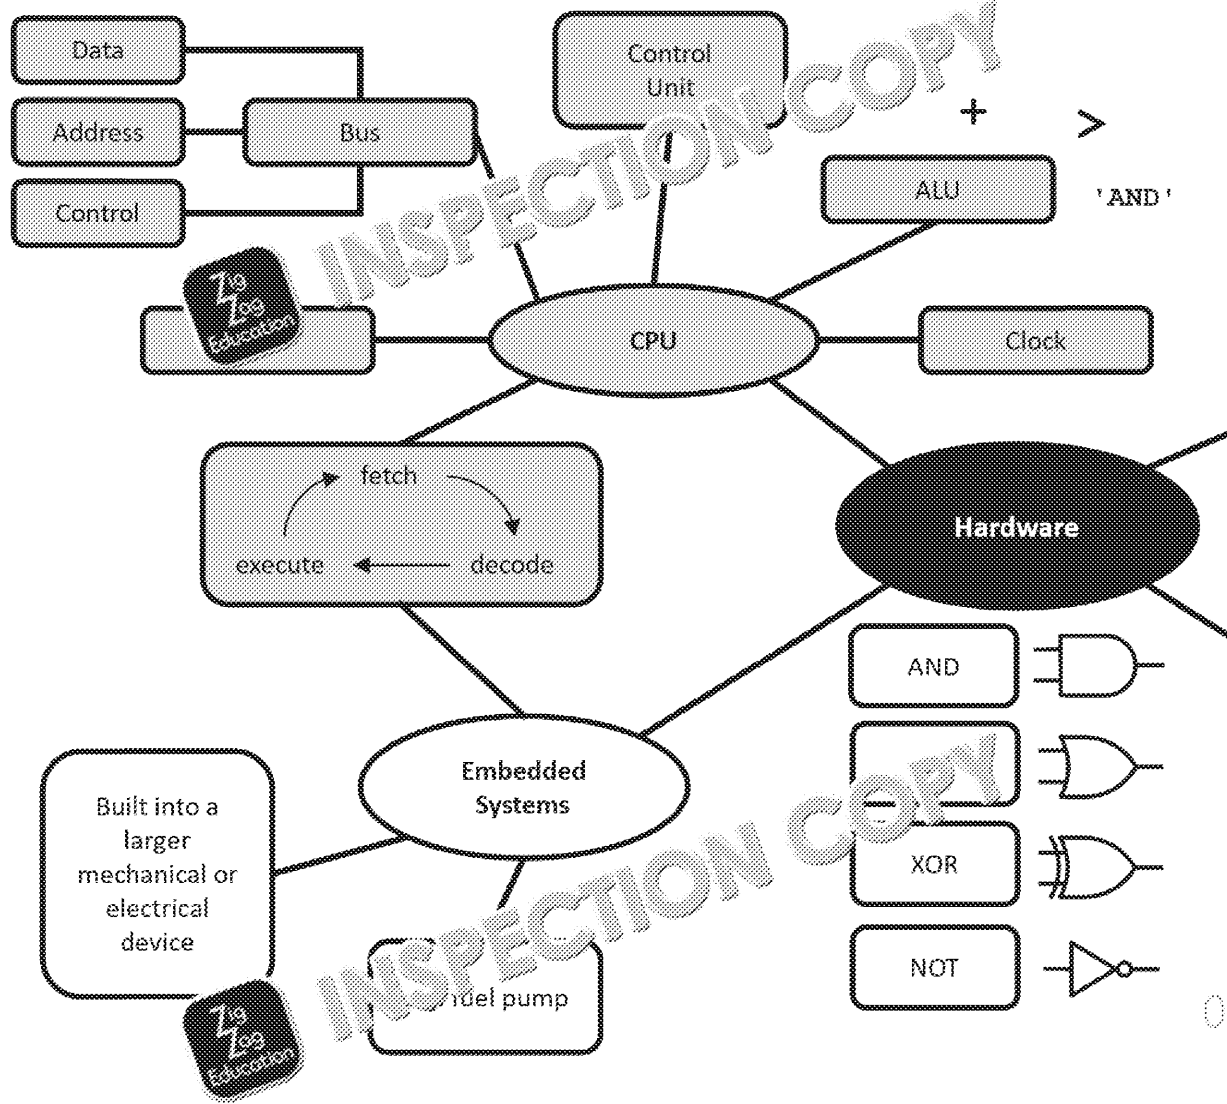

Embedded system – a computer that is built into a larger mechanical or electrical system, such as a microwave oven or a washing machine. Embedded systems are used when a general-purpose computer is not viable (as in a microwave) or when they have only a single, specific purpose.

Examples of embedded systems are kitchen appliances (microwaves, washing machines), consumer electronics (watches, fitness trackers) and subsystems of vehicles (entertainment systems, climate control systems).

3.5. Fundamentals of Computer

Network – an interconnection of computers and other pieces of hardware for communication and the sharing of resources.

- | | |
|--|--|
| <ul style="list-style-type: none"> + Resources, such as printers, Internet connections and files can be shared, saving both money and effort + Communication can take place, via email or instant messaging + Backing up data to a different computer is far more straightforward | <ul style="list-style-type: none"> - Management of a network can be quite expensive - Security procedures to prevent unauthorised access to computers - Network hardware, such as routers, can be expensive |
|--|--|

Types of Network

PAN – Personal Area Network. This is for a single user, connected via Bluetooth, infrared, and headset.

LAN – Local Area Network. This is a network within a building or perhaps a campus. Usually, the hardware that belongs to a LAN.

WAN – Wide Area Network. This covers a large geographic area, with shared ownership. A telecommunications company might own a WAN. The Internet is the largest example of a WAN.

Networks can be either **wired** or **wireless**:

| Wired | |
|---|--|
| | |
| <ul style="list-style-type: none"> + More secure, as a physical connection is needed, so a hacker would need to be in the building + Less prone to interference | <ul style="list-style-type: none"> + Much easier to add new computers + No requirement to run cables |

| Wireless | |
|-----------------|--|
| | |
| Wireless | Radio waves |
| Wired | <p>Optical fibre can be used for very fast connections, or if lots of computers are connected on a single connection.</p> <p>Copper cabling is cheaper and slower, although it is quick enough for a single computer would perform online.</p> |

INSPECTION COPY

**COPYRIGHT
PROTECTED**

Topologies

Network topology – the pattern in which the hardware on a network connects. Common topologies include star and bus.

| Topology | Explanation |
|---|---|
| <p>R = router (connection to the Internet) S = switch</p> | <p>Star</p> <p>Every device is connected to a switch and all communication travels via this switch.</p> <ul style="list-style-type: none"> + Very few data collisions, since each device has its own connection to the switch + Strong, centralised security - Lots of cabling needed - If the switch has no spare ports, adding more devices can be difficult |
| | <p>Bus</p> <p>A central cable, called the backbone, has terminators (black rectangles), connected to both ends.</p> <ul style="list-style-type: none"> + Uses relatively little cable, making it easy to install + Additional devices can be easily added - Collisions can occur, as multiple traffic can travel along the shared backbone - If a large number of devices are connected, the network can be slow (due to collisions) - If the backbone is cut, no signals can travel and the network is no longer fully connected |

Network Protocols

Protocol – a set of rules that governs how a computer communicates. There are many protocols, each necessary for a different purpose (email, access to the Internet, etc.). Without protocols, communication between computers would be impossible.

- **Ethernet** - (a family of protocols rather than a single protocol). This is a set of rules that governs how data is formatted for transmission across a local area network.
- **Wi-Fi** - these letters actually aren't short for anything but are a brand name for a technology that transmits data on a wireless local area network (WLAN).
- **TCP/IP** - These are two protocols that often work together – *Transfer Control Protocol* and *Internet Protocol*. Their collective role is to break up data into packets, each of which is a chunk of data that is sent from one device to another, and where it is sent and delivered to.
- **UDP** – *User Datagram Protocol*. This protocol transmits data packets very quickly but does not check whether they are received, so it is not always reliable.
- **HTTP** – *Hypertext Transfer Protocol*. This is the set of rules governing how how data (web pages, etc.) is moved around the Internet, from device to device.
- **HTTPS** - *HTTP Secure*. This protocol encrypts data that is sent across the Internet so that it cannot be read if intercepted, so is favoured when sending passwords or credit card numbers.
- **FTP** - *File Transfer Protocol*. This is how files are moved from one computer to another. This protocol is heavily relied upon in building websites, moving files from the server, from where they can be accessed publicly.
- **SMTP** - *Simple Mail Transfer Protocol*. This is used to forward emails from one computer to another.
- **IMAP** - *Internet Message Access Protocol*. This email protocol is used to allow devices (like tablets, phones, etc.) to access the same email account.

**COPYRIGHT
PROTECTED**

Network Security

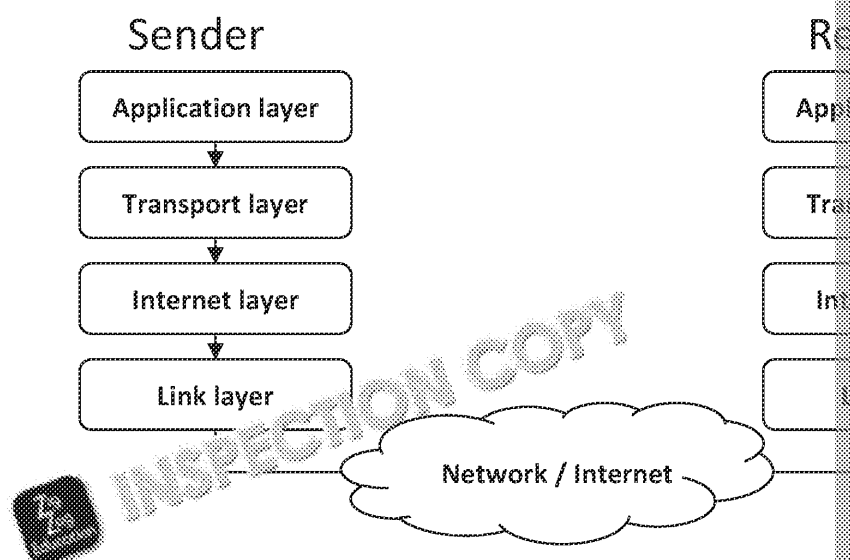

With more data being shared, more data is falling into the wrong hands. Organisations need professionals to keep data secure, as data breaches can damage an organisation's reputation. Even an individual can lose out financially if their credit card details are stolen.

| | |
|------------------------------|---|
| Authentication | Measures to make sure that a person trying to access a network is who they say they are. This can take place by way of: <ul style="list-style-type: none"> • Usernames and passwords • Memorable information, such as their mother's name • Checking that they are using a recognised IP address |
| Encryption | Scrambling data using a key to ensure that it makes no sense if intercepted. When it is received, the recipient also uses the key to decrypt the data, returning it to its readable form. |
| Firewalls | Firewalls can be either hardware, software or both. A firewall can filter out certain traffic (such as all emails or any traffic from a particular country) and allow certain traffic (such as from a single, trusted device). |
| MAC address filtering | Each computer has a MAC (media access control) address. This address, once assigned, cannot be changed. Based on this unique identifier, a network can either permit or block traffic from a particular device. |

TCP/IP stack – a series of protocols. When they work together, they allow a computer to communicate through any number of pieces of network hardware, to another computer. The stack is a *concept*, not a physical thing.

This stack has four layers, each containing a number of protocols. When data is sent down the stack and repackaged the data into smaller units, before passing the data to the network. When received, those units are reassembled as they move up the stack.

COPYRIGHT
PROTECTED

| Layer | Description |
|--------------------------|--|
| Application layer | Where network applications, including browsers and email applications, operate. |
| Transport layer | Establishes communication between the sender and the recipient, agreeing on how communication will take place. |
| Internet layer | Packages data for transmission, by breaking it into units called packets , which are sent across the network. |
| Link layer | The physical components of the computer, such as the network interface card, operate at this level. |

Note that some resources, particularly if they are not AQA-specific, might use slightly different layer names. In an AQA exam, you should use the names in the table above.

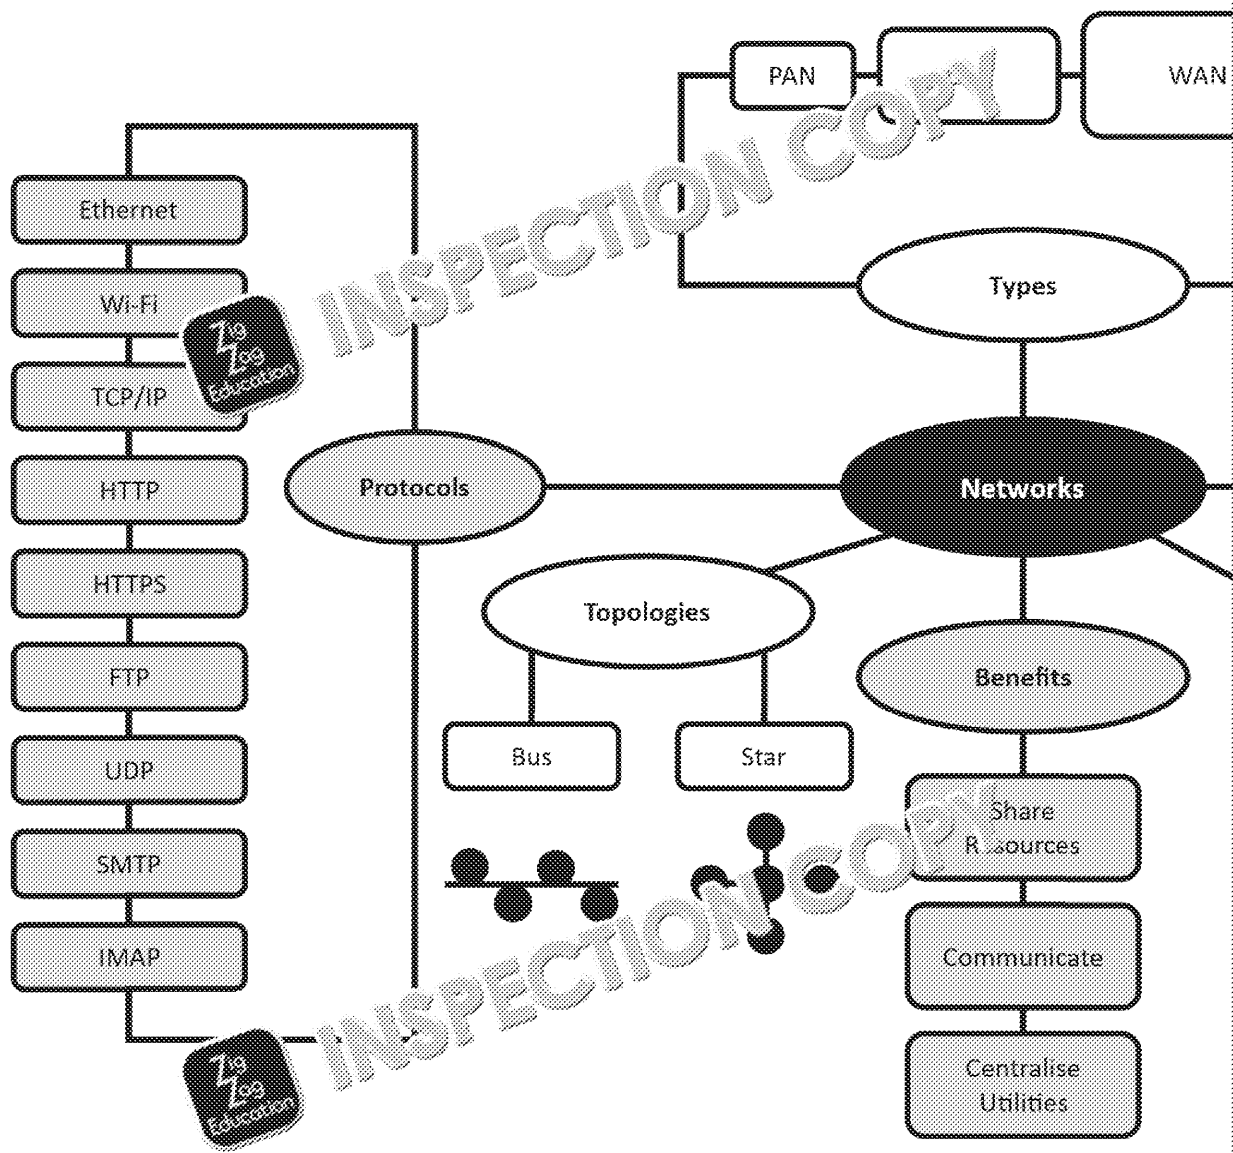

There are benefits to developing systems using this model:

- Different developers can be assigned to different aspects of a system
- Part of a system can be removed and altered without affecting the rest of the system

3.6. Cyber Security

3.6.1. Fundamentals of Cyber Security

Cyber security – a series of processes, practices and technologies that protect software and data from attack, damage, or unauthorised access.

3.6.2. Cyber Security Threats

Social engineering – forms of cyberattack that focus on people, rather than the weak point in any system. There are different ways to manipulate confidential information.

- **Pretexting** involves fabricating a scenario in order to gain unauthorised access. A person might pretend to be from IT support in order to persuade an employee to give them their password.
- **Shoulder surfing** or **shouldering** is simply watching, over someone's shoulder, for their PIN or password.
- **Phishing** uses emails or SMS messaging to lure people to convincing but fake websites. They are logging in, but they're really transmitting their login details to an unknown person.

1

you@mail.com

Your account has been compromised. Click [here](#) to reset the password.

2

YourBank

user

password

OK

Yes

No

1. The victim receives an email with a hyperlink. The email tells the user that their account has been compromised and that they should click the hyperlink, often saying that their security has been compromised in order to get them to act quickly.
2. They will be taken to a screen that asks them to enter personal information. This screen is identical to a screen with which they are familiar.
3. When they have entered the information, they are usually forwarded to a legitimate website. In the meantime, the information they have entered has been forwarded to a hacker.

Malicious software (malware) – any program that works against the interests of the user. Trojans, adware and spyware are types of malware, although they are not all created equally.

- **Computer viruses** are self-replicating pieces of code that can damage data or spread via email attachments or removable media such as USB flash drives.
- **Trojans** or **Trojan horses** are legitimate programs developed with the intention of being useful. Since they are largely legitimate, they are often not recognised as malware.
- **Spyware** covertly obtains sensitive data, such as credit card numbers and passwords, and transmits it to a hacker across the Internet.

INSPECTION COPY

COPYRIGHT
PROTECTED

Weak passwords – passwords that are easy to guess. \$tR0nG p@5\$w is longer than weak passwords. Similarly, **default passwords** can be a problem as users might not change the password from 'admin' or 'password' when they log on, leaving the network vulnerable.

Pharming – redirecting users to an unsafe site. They might type in the bank, and be taken to a website that looks very much like their bank's website, then collect the user's login credentials.

Misconfigured access rights – access rights are permissions that tell a computer which files and other resources it can access. If these access rights are misconfigured, employees and other users could access data that they should not be able to.

Portable media – any storage device that is highly portable can easily be lost or stolen, and introduce malware onto a system.

Unpatched software – when a security risk is identified in a program, a **patch**, which is an add-on program that fixes the security risk, is released. If a user does not install the patch, their computer is not secure.

Threats will often exist in combination. A username acquired via phishing could be used with a weak, easy-to-guess password to introduce a virus that specifically seeks out unpatched software.

**COPYRIGHT
PROTECTED**

3.6.3. Methods to Detect and Prevent Cyber Security Threats

| | |
|-----------------------------------|---|
| Biometric measures | <p>Using some part of a person's biology to access a system instead of a password.</p> <ul style="list-style-type: none"> • Mobile phones and tablets that unlock on scanning a fingerprint • Doors that unlock when a person's iris or retina is scanned • Voice recognition • Face recognition |
| Password systems | <p>Automated procedures that ensure that sound password policies are followed.</p> <ul style="list-style-type: none"> • Passwords that include many different characters, such as \$tR0ng p@s\$word\$ and a minimum number of characters • Passwords that must be changed on a regular basis <p>Users that try not to adhere to the policies are simply not allowed access.</p> |
| CAPTCHA | <p>A distorted image is presented to the reader, which is easy for a human to read but difficult for a computer. This technology is used to ensure that a human is reading the image and not a computer program trying to guess a password at a rate of millions per second.</p> |
| Email confirmation | <p>Often, when a password is changed, a user must verify this change by clicking a link sent to a registered email address. This can prevent third parties from changing a password.</p> |
| Automatic software updates | <p>When a new version of software is released, which might have security improvements, a computer can be configured to automatically download and install the updates.</p> |
| Penetration Testing | <p>Someone tries to hack into a system, but as an employee of the system owner. Their aim is not to steal or corrupt data, but to identify weaknesses that can be resolved.</p> |

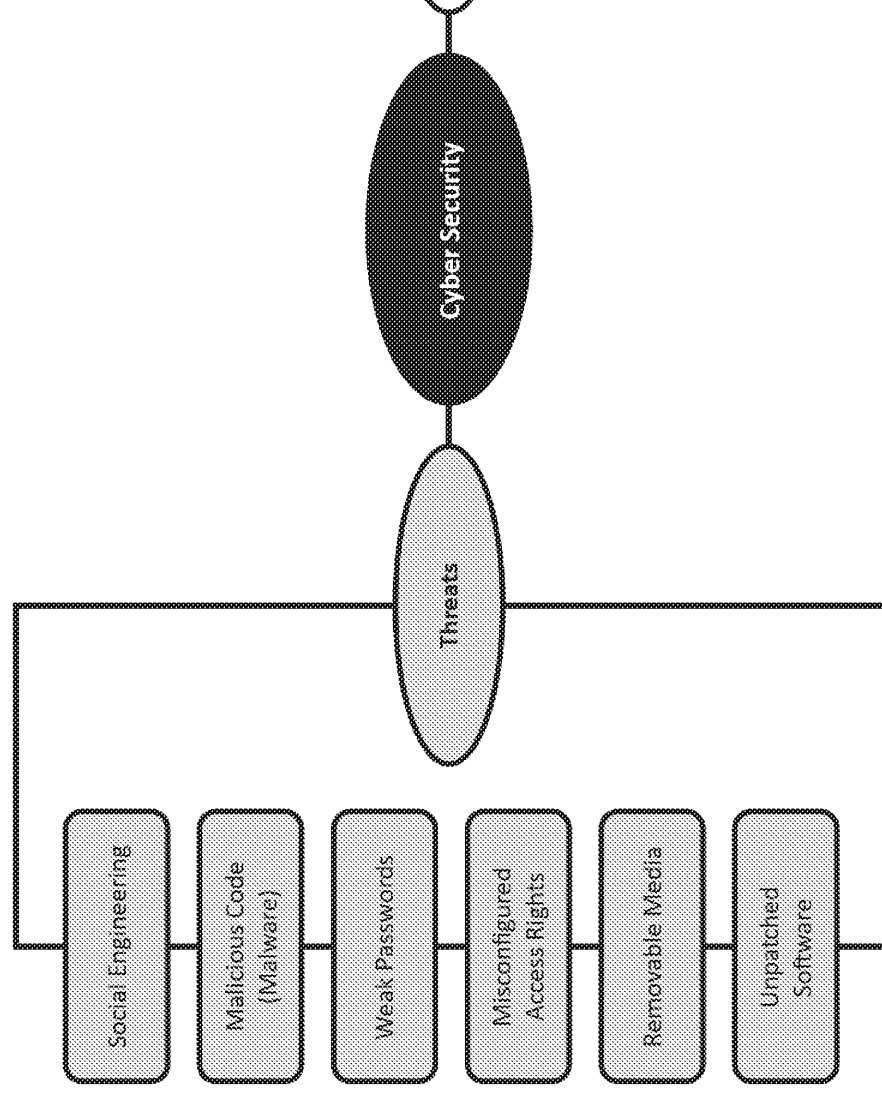

If a person is conducting penetration without the consent or knowledge of the system owner, that person is more likely to be a threat than a defence.

3.7. Relational Databases and

3.7.1. Relational Databases

Database – a collection of related data items stored systematically in a way that can be retrieved from one or more of several key elements, some of which are described below.

The **table** below stores data relating to video games.

| Stock No | Title | No in Stock | Supplier No |
|----------|----------------|-------------|-------------|
| A00123 | Frostpunk | 17 | X01 |
| A00124 | Stardew Valley | 12 | X02 |
| A00125 | XCOM 2 | 1 | X03 |
| A00126 | Wasteland 3 | 7 | X04 |

Within this table there are four **records**. A record is one instance of something. In this case, video games, each record consists of everything we know about **one** video game. Every row in the table (its stock number, title, number in stock and supplier number) is one record. Every row represents a different game. Stardew Valley is another record.

There are also four **fields**, namely *Stock No*, *Title*, *No in Stock*, and *Supplier No*. A field is a single piece of information about each record. Each field has a **data type**, which corresponds to the programming language used. Data can be numeric, text-based, or date/time, among others.

One field, *Stock No*, is the **primary key**. This is the field that uniquely identifies each record. For example, the record identified by the stock number A00124. Since this is the primary key, no other record can have the same stock number.

Relational database – database in which data is organised into multiple tables, each representing an entity, which could be anything about which we need to store data. Links between these tables, called **relationships**, allow for quick retrieval of data. Relational databases allow for the elimination of **data inconsistency** (the same data stored in other data) and **data redundancy** (the same data stored more than once).

Tables can also contain one or more **foreign keys**. A foreign key is a field. It is a field in one table which is used to create relationships. In our table, *Supplier No* is a foreign key, as it refers to the primary key in some other table:

| Supplier No | Supplier Name | Supplier Phone |
|-------------|-------------------|----------------|
| X01 | 11 Bit Studios | (1111) |
| X02 | Concerned Ape | (2222) |
| X03 | Double Fine Games | (3333) |

As this would be a relational database, we could extract data from both tables to see that we have a total of 24 games in stock, or that we should call (3333) to order more copies of XCOM 2.

3.7.2. Structured Query Language (SQL)

SQL – Structure Query Language is used to view and manipulate the data in a database, as well as to create and remove tables.

All SQL commands in this chapter relate to the following database table, which is

| StudentID | LastName | MathsScore |
|-----------|----------|------------|
| S123 | Evans | 87 |
| T456 | Green | 62 |

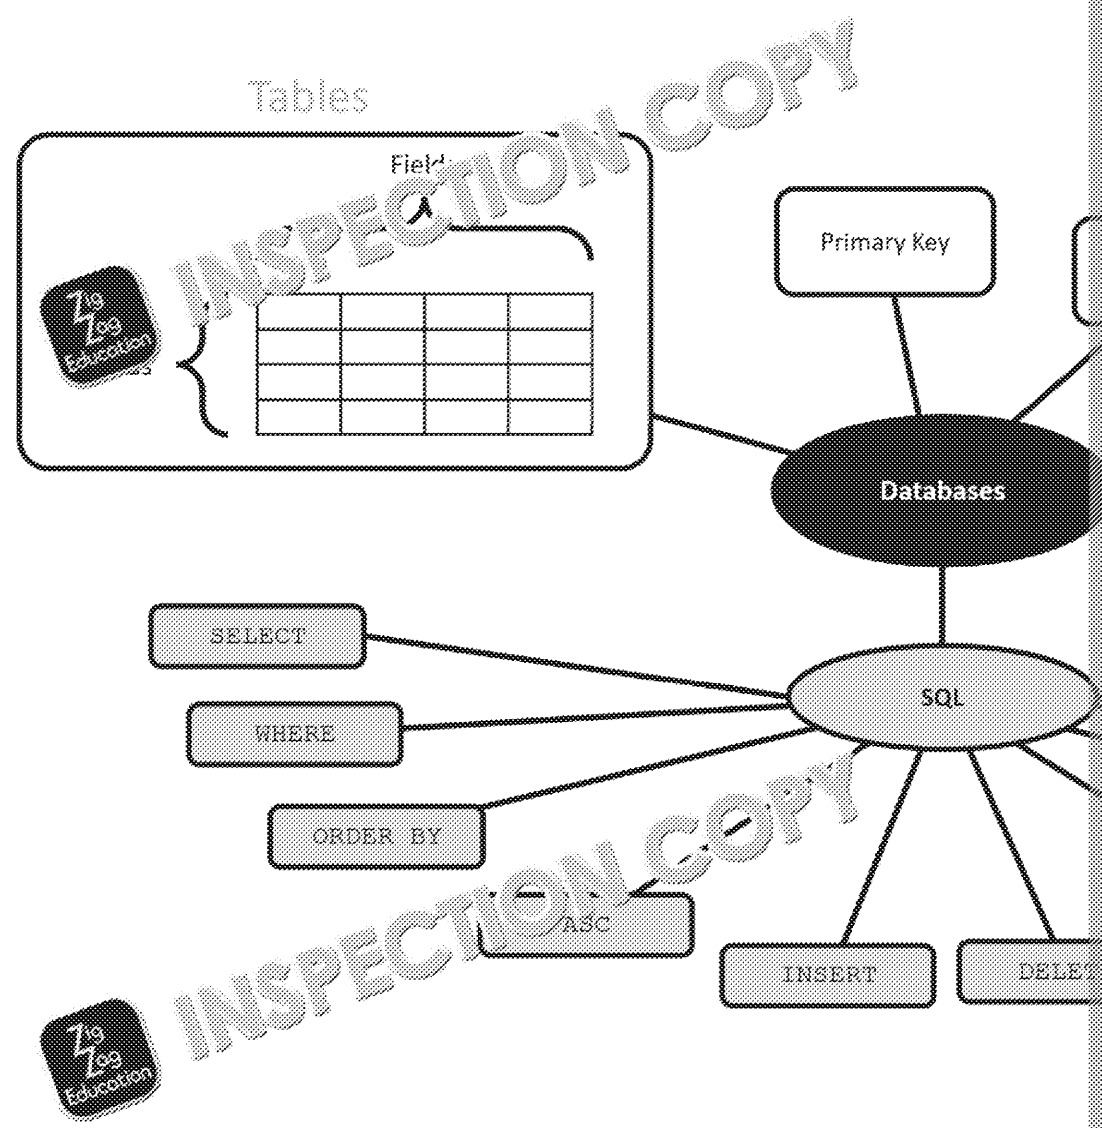

The fields *StudentID* and *LastName* are *varchar* format, while *MathsScore* and *EnglishScore* are *int* format. *EnglishScore* does not distinguish between integer and real numbers, and treats them in the same way.

| SQL statement | Description |
|---|---|
| <code>SELECT * FROM student</code> | Reads everything from the table. The table name is unchanged. The * symbol means 'all'. <i>student</i> is the name of the table. |
| <code>SELECT * FROM student ORDER BY LastName ASC</code> | This would read everything from the table, but the results in ascending alphabetical order based on <i>LastName</i> . If we were to use <i>EnglishScore</i> instead, it would still work, as this is also a number. |
| <code>SELECT * FROM student ORDER BY MathsScore DESC</code> | This would read everything from the table, but the results in descending order based on <i>MathsScore</i> . |
| <code>SELECT MathsScore FROM student</code> | Reads the named field, <i>MathsScore</i> , from the table, ignoring other fields. This would give the average score, where other fields are ignored. |
| <code>SELECT LastName FROM student WHERE MathsScore > 80</code> | Reads the last names from the table where the <i>MathsScore</i> is greater than 80. |
| <code>SELECT MathsScore FROM student WHERE StudentID = "T456"</code> | Reads the <i>MathsScore</i> of the student with <i>StudentID</i> 'T456'. Notice how text (T) is in single quotes, but numbers (80, in the previous example) are not. |
| <code>INSERT INTO student (StudentID, LastName, MathsScore) VALUES ("U789", "Jones", 50)</code> | Create a new record. The first part lists the fields, and the second part lists the data to be entered into the table. Notice that this would leave a new record. |
| <code>UPDATE student SET MathsScore = 88, EnglishScore = 55 WHERE StudentID = "S123"</code> | Edit one or more existing records. In this case, the <i>StudentID</i> or S123 will have their <i>MathsScore</i> and their <i>EnglishScore</i> set to 88 and 55 respectively. |
| <code>DELETE from student WHERE StudentID = "T456"</code> | Delete any records with a <i>StudentID</i> of T456. That's just one student. In this case, it would delete no records, one record. |
| <code>DELETE from student</code> | Without the WHERE clause, it would delete all records from the table, but the table itself would remain. |

Sample Examination-style Questions

20. A database is used to monitor the attendance and punctuality figure of students. The records of the **performance** table are displayed below:

| Student_ID | Last_Name | First_Name | Gender | Attendance |
|------------|-----------|------------|--------|------------|
| P1 | Adams | Megan | F | 96 |
| P2 | Ali | Raza | M | 98 |
| P3 | Jones | Timothy | M | 95 |
| P4 | Smith | Sam | M | 97 |
| P5 | Williams | Emily | F | 94 |

Write SQL commands to carry out the following operations:

- Retrieve the student ID and attendance for all students.
.....
- Remove student *P3* from the database completely.
.....
- Adjust student *P1*'s punctuality value from *96* to *95*.
.....
- Create a new record with Student_ID of *P6*, Last_Name of *Smith*, and attendance of *99*.
.....
- Retrieve all student data for students with attendance below *90*.
.....

3.8. Ethical, Legal and Environmental

Ethics – this term refers to what is right and what is wrong, although it is not always straightforward that they have a single 'right' answer. Often what is right for society as a whole, and vice-versa.

| Topics | Issues |
|---|---|
| Privacy  | <ul style="list-style-type: none"> People expect to go online and find out everything about others (freedom of expression), but they might prefer to keep some elements of their lives (expectation of privacy) away from the government. On the other hand, arguments that the government needs access to personal data to fight terrorist threats. Once something is shared online, particularly in the work environment, it is not possible to delete it completely. Through social media, people unwittingly share details of their lives, including where they go in the evening, where they live, and where they work, attended by their children, where they go in the evening. |
| Inclusion | <ul style="list-style-type: none"> Among some groups, especially those of school age, there is a concern about not having the latest technology. Not everyone in the country has access to the Internet, which limits access to information, to job listings or to a society that is increasingly digital. Government could commit money to solving this inequality, but this would be spending money unequally. This is an instance where there is no 'right' answer. |
| Professionalism | <ul style="list-style-type: none"> There is increasingly an expectation of people to be available outside of working hours; this is a direct impact of technology. Although you can apply for jobs internationally, employers are making the process far more competitive. Social media can be seen by anyone, including prospective employers, blurring the line between private and professional life. |
| Artificial Intelligence | <ul style="list-style-type: none"> Driverless cars are now a real possibility, but it might be difficult to determine if the occupant or its programmer would be to blame in the event of an accident. Computers can read CVs to filter out certain types of jobs, which might be people from particular postcode areas or ethnic groups. This is an instance where an unscrupulous developer decides upon this. |

INSPECTION COPY

INSPECTION COPY

**COPYRIGHT
PROTECTED**

Legal – this term refers to what is lawful and what is not. Laws are what govern the normal functioning of a society, but it can be difficult to write a law that either doesn't exist yet, or is constantly changing. Applicable law

Copyright, Designs and Patents Act (1988)

This law protects **intellectual property**, meaning it is a criminal offence to copy without the permission of the owner of the **intellectual property rights**. Different types of

- Copyright applies to anything that can be written (such as web pages, books, music, and images). Once something has been written, copyright exists immediately and applies for it.
- A registered design (applicable to computer graphics) would apply to logos and suggests, such images need to be registered and they need to have been used in a product.
- Patents can be used to protect inventions. This would apply to a piece of new machinery or a new method of doing something, but not to program code.

Computer Misuse Act (1990)

This law makes hacking a criminal offence. The following activities are recognised as criminal:

- Accessing material on a computer that you are not authorised to access (for example, using someone else's credentials)
- Modifying material on a computer that you are not authorised to modify. If you are allowed to access the data, you are not allowed to modify it.

Data Protection Act (2018)

This law applies to personal data of living individuals. If an organisation stores personal data about individuals, that data must be...

- processed fairly and lawfully
- adequate, relevant and not excessive
- not kept for longer than necessary
- held for specified purposes
- kept up to date, accurate and complete
- kept secure

A **data subject** (a person about whom data is stored) has rights under this law:

- They should be informed about how their data is used
- They should be able to access their own personal data
- They have the right to have inaccurate data corrected
- They can have data erased, and processing stopped or restricted

Freedom of Information Act (2000)

This law gives members of the public the right to access information under the control of public bodies.

- The information must relate to either a public body (local council, government department, or an organisation that provides a service to a public body)
- Providing the data would not cause a breach of the law (probably the Data Protection Act)

You are not required to have knowledge of specific laws. It is much more important to understand the legal principles than the laws themselves.

**COPYRIGHT
PROTECTED**

Environment – a broad term with several meanings relating to the physical world. Global air pollution is an environmental issue, but so is the distance between your home and where you work.

Health Issues

- | | |
|--|---|
| <ul style="list-style-type: none"> + Proliferation of health-tracking apps allow people to monitor exercise and calorie intake – people are better informed + Medical technology is continually advancing in predicting and diagnosing illness + Sharing of health-related data across the Internet helps research. | <ul style="list-style-type: none"> - An increase in computer use has led to an increase in sedentary lifestyles - Some people are addicted to social media, and they cannot stop using it - Technology means that people can work from home, increasing the distance from work, increasing pollution |
|--|---|

Energy Use

- | | |
|---|--|
| <ul style="list-style-type: none"> + Computers and other devices can be used to reduce consumption of fossil fuels; they can turn off lights in empty offices and cause cars to run more efficiently + Smart meters allow people to track and control their use of electricity and gas at home and at work + People can work from home more, so they commute less. | <ul style="list-style-type: none"> - Computers, tablets and other devices all consume electricity - The manufacture of electronic devices requires electricity - Many devices that are not seen, including cloud storage and data centres, consume a lot of electricity |
|---|--|

Resources

- | | |
|---|---|
| <ul style="list-style-type: none"> + In theory at least, less paper needs to be used, so fewer trees should be cut down + Some products, such as books and music, can be delivered electronically, with no physical transport needed + One delivery driver, delivering ten Internet-ordered products on a single delivery run, requires less fuel than ten people each driving to a shop for one item. | <ul style="list-style-type: none"> - In reality, people still use a lot of paper, and may not really be saving trees - Computers require a lot of energy to produce, such as the mining of rare earth metals for supply and have to be replaced regularly - Not all obsolete technology is recycled; some of it ends its life, polluting the environment |
|---|---|

All of the bullet points in this chapter are just the beginnings of arguments. Be prepared to come up with two conflicting ideas against each other to see which one carries the most weight.

Exam questions on this area will require you to draw together an understanding of the **ethical, legal and environmental** impacts in a single answer. While you are expected to understand the areas mentioned in the table below, you are also expected to think about other areas that are particularly relevant. You might be asked about, say, wireless networking, and you are expected to recognise that unauthorised access or invasion of privacy are relevant issues. These bullet points are starting points – not whole answers.

INSPECTION COPY

**COPYRIGHT
PROTECTED**

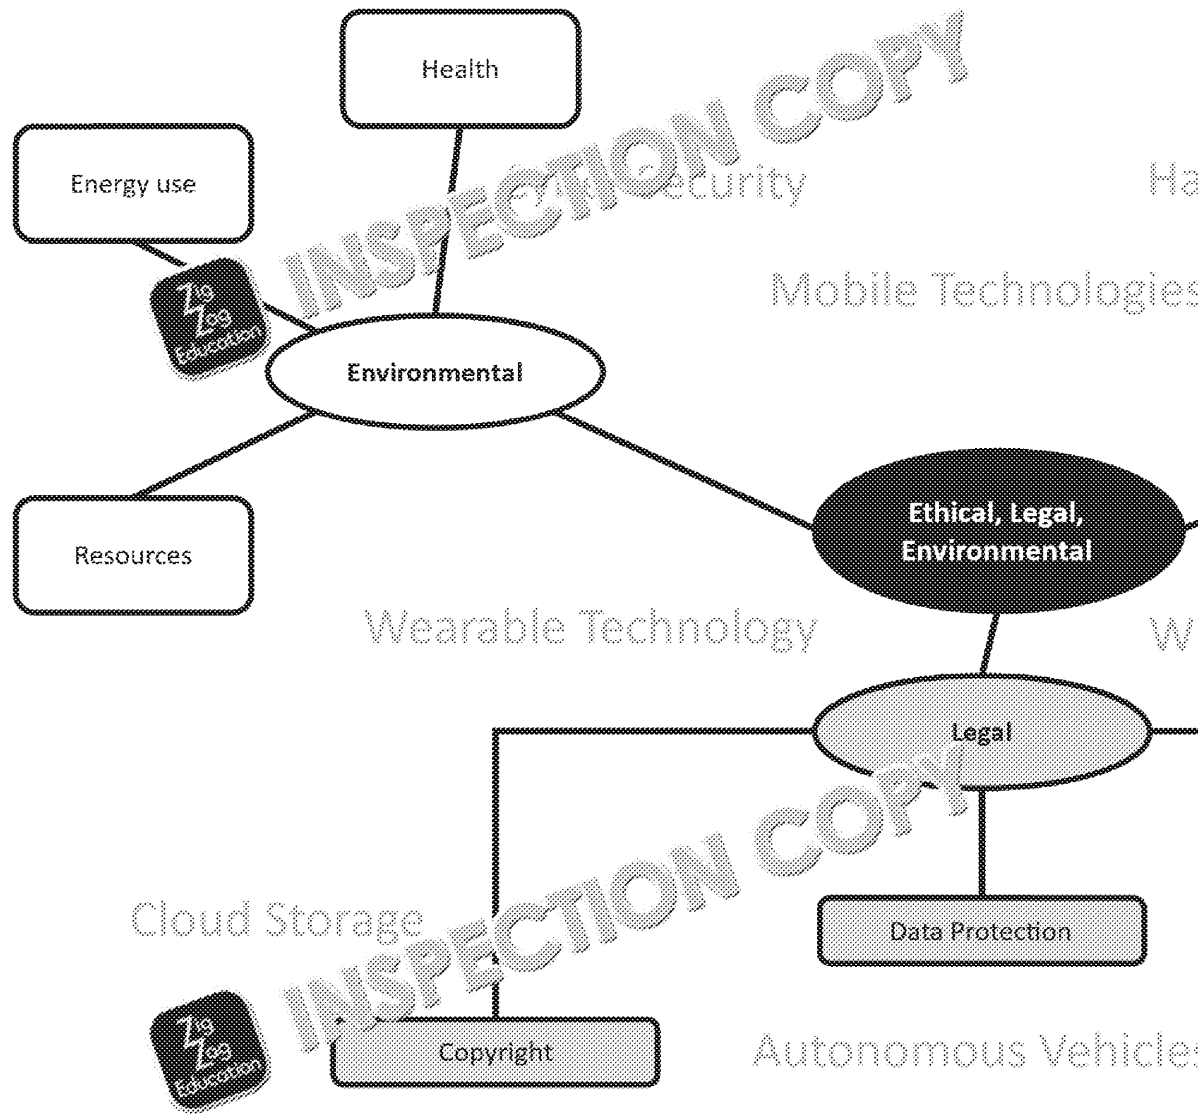

| | |
|--|---|
| Cyber security | <ul style="list-style-type: none"> A government cyber security policy may actually grants them access to personal data A company may be held liable if they do not protect access; they can be sued for a data breach The issue of cyber security overlaps with many other mobile technologies, wireless networking and cloud storage |
| Mobile technologies | <ul style="list-style-type: none"> The amount that your phone knows about you, in terms of location, contacts, etc. might already be a breach of privacy Constant replacement of mobile phones, and their impact on the environment Illegal copies of mp3s are commonly found on people's phones |
| Wireless networking | <ul style="list-style-type: none"> Easier access for unauthorised users than in a wired network Wireless networking is better in terms of the environmental impact, but network hardware is concerned Privacy can be breached as others might access the network |
| Cloud storage | <ul style="list-style-type: none"> Other people may gain access to your data when stored in the cloud Providers must adhere to the Data Protection Act Fewer, more centralised data stores are better for reducing transport costs associated with distribution |
| Hacking | <ul style="list-style-type: none"> Unauthorised access potentially breaches people's privacy It's possible that data obtained as a result of hacking is used for the greater good Hacking often results in additional crimes, such as identity theft |
| Wearable technologies / Computer based implants | <ul style="list-style-type: none"> Wearable technologies carry the same ethical, legal and security issues as mobile technologies (see above) Implants carry the additional complication of replacement, which is not as straightforward as simply buying a new one Looking to the future, an implant may be a potential security risk, as it could contain biometric data, information about its user, and the device could be dangerous |
| Autonomous vehicles | <ul style="list-style-type: none"> In the event of a collision, who bears legal responsibility? (Is it the driver, or the programmer who wrote the code?) Split-second decisions can be deliberated on slowly, and then coded into the vehicle's control system. Who should make the decision as to who to hit, and how to control, should safeguard the lives of its occupants? An advantage of autonomous vehicles is that they can be programmed to plan their acceleration and braking to potentially reduce carbon emissions. |

These issues are not straightforward, and there are often multiple viewpoints, so you'll get more out of exploring the issue in detail than arriving at a clear and possible solution (you'll be able to do both).

PROTECTED**

Sample Answers

3.1. Fundamentals of Algorithms

1. An algorithm is a series of instructions that describes how to solve a specific problem.

i

As you've seen by this point, this guide is full of definitions. It is highly likely that definitions will be required in the exam, although it's impossible to determine which ones, assuming you have revised well, are the easiest marks available. One way to remember definitions is to use flash cards, with the word on one side and its definition on the other. Making them your own, and it's easy for others to help you to study by testing you on the definitions.

2. Terminator Process Decision
3. Pairs of numbers are compared (first with second, second with third, third with fourth, etc.) being switched if they are not in order. Once all pairs have been compared, a new pass is made until either n-1 passes have occurred, or an entire pass occurs with no numbers being swapped.

i

This explanation is fairly complex. In circumstances like this, you might find a written answer with a diagram. While it probably wouldn't be worth any marks, it could clarify any points that you haven't worded as well as you would have liked.

3.2. Programming

4. a. i. total iv. >
 ii. keeps a running total v. WHILE
 iii. +
 b. They would need to input a value of '-1' or less.

i

The best way to prepare for questions like this one is to write code – lots of it. When writing a program, you should make an effort to understand every part of every line of code. It's not just about simply having a program that works; make sure you can understand *why* it works. Don't just copy and paste any lines of code that you don't understand.

- 5.

| Data | Integer | Real | Boolean |
|--|---------|------|---------|
| Money in account | | ✓ | |
| Account holder's name | | | |
| Number of whole years the account has been active | ✓ | | |
| Account holder's position | | | |
| Whether or not an overdraft is permitted | | | |
| A single character code that identifies the account type | | | |

6.

```
highCount = 0
for x in data:
    if x > 5:
        highCount += 1
print(highCount)
```

INSPECTION COPY

COPYRIGHT
PROTECTED

3.3. Fundamentals of Data Representation

7. a. $128 + 16 + 8 + 2 + 1 = \underline{155}$
 b. $1001 = 9$; $1011 = B$; 9B

You will probably be asked to convert between binary, denary and hexadecimal at the end of the exam, if you have time, a good way to check your answers is to reverse. Did you convert a binary number to hexadecimal? Convert it back to see if the result of this conversion matches the question.

8. a. 01100000
 b. Number is multiplied by four.
 c. Overflow would occur. There are not enough bits in this number to store the result.
9. a. A collection of every possible letter, number, symbol, etc. available to a computer.
 b. 77
10. a. i. number of different colours possible within a particular image
 ii. number of different colours possible within a particular image
 b. $640 * 480 = 307,200$ bytes
 $307,200 / 1,000 = \underline{307.2 \text{ kilobytes}}$

When you try exam questions that require calculations, make sure you show only if it is a comprehensive attempt at every single mark, it increases the likelihood of getting marks, even if your calculations contain an error.

3.4. Computer Systems

11. a. AND
 b.

| Q | P | Output |
|---|---|--------|
| 0 | 0 | 0 |
| 0 | 1 | 0 |
| 1 | 0 | 0 |
| 1 | 1 | 1 |

12. An embedded system is a computer that forms part of a larger electrical or mechanical system. Examples include microwaves and petrol pumps.

13.

| Component | Description |
|-----------|---|
| Optical | '1's and '0's are represented by pits being burned or not burned into specific locations on a disc |
| Magnetic | '1's and '0's are represented by magnetising individual bits of tape which can be either North-aligned or South-aligned |
| State | Transistors can either hold a charge or not hold a charge, representing either a '1' or a '0' |

**COPYRIGHT
PROTECTED**

14. One role is the management of hardware. The operating system is responsible for managing input and output devices, which it can only do if the correct drivers are installed. It also manages processes. When lots of tasks require the processor's attention, it is the job of the operating system to prioritise and decide the order in which they should be executed. A third role is the management of files. An operating system allows the user to add, delete or edit files, and also decide where each file is to be stored.

i

Questions that begin with the term 'describe in detail' need to be addressed in detail. With these questions, the mark schemes usually give the examiners suggestions of which points are worth a mark. The alternative, listing every possible answer or trying to cover every possibility, is impractical. This counts in your favour, but it doesn't do any harm to aim for maximum marks. Where there's a 6-mark 'describe-in-detail' question, aim for 9 marks.

3.5. Fundamentals of Computer Networks

15. a. A protocol is a set of rules governing how one device communicates with another device.
b. Simple Mail Transfer Protocol. This is used to forward emails from one mail server to another.
– Internet Message Access Protocol. This allows email messages to be accessed from a mail client accessing the same email account.
16. Networked computers can share resources such as printers.
Networked computers can communicate with one another using email or instant messaging.
Networked computers can centralise backing up, making data loss access more difficult.

i

This was a 3-mark question, so three pieces of information are required. If each mark is coming from, you should address each mark separately. Since the question asks for three distinct points, three distinct sentences are the best way to present your answer.

17.

| | Internet Protocol | File Transfer Protocol |
|-------------------|-------------------|------------------------|
| Application Layer | | ✓ |
| Transport Layer | | |
| Internet Layer | ✓ | |
| Link Layer | | |

3.6. Cyber Security

18. People can read staff members' passwords over their shoulders. This can be prevented by using passwords, using a range of different characters and symbols which are more difficult to guess.

Data can be intercepted as it is transmitted between devices. Encryption can be used to prevent this by scrambling data so that it only makes sense when accessed on the intended device.

Malware can be installed on a system, which could steal or corrupt patient data. Regular updates and antivirus software is installed and kept up-to-date is a means of countering this.

i

Again, the origin of each mark is easy to identify. Each paragraph is an example of a problem-solution paragraph. Each paragraph needs to make two distinct points. Within each paragraph, the first sentence describes the problem (first mark) and the second sentence describes the solution (second mark).

COPYRIGHT
PROTECTED

19. a. Social engineering is the act of manipulating people in order to extract information.
- b. One example is phishing, another is shoulder surfing.

The keyword 'state' means only minimal information is required. In 'state' phrase will be enough to get you the mark.

3.7. Relational Databases and Structured Query Language (SQL)

20. a. `SELECT Student_ID, Attendance FROM performance`
- b. `DELETE FROM performance WHERE Student_ID = 'P3'`
- c. `UPDATE performance SET punctuality = 95 WHERE Student_ID = 'P3'`
- d. `INSERT INTO performance (Student_ID, Last_Name) VALUES ('P3', 'Smith')`
- e. `SELECT * FROM performance WHERE attendance < 90`

3.8. Ethical, Legal and Environmental Impacts

21. The main benefit is that more people are now able to communicate with each other. Communication is possible between countries, and people have access to information wherever they go. There are also benefits to safety for a person who is in danger to seek help. While some may question the new and improved mobile phones, whenever someone gets a new phone, they give up their old phone from them. This increases the number of people who have access to safety benefits.

However, there are some negative points. Mobile phones make it much easier for privacy at risk, since photos and personal information shared on social media can be completely remove from the Internet. There is also an ethical issue of equal access. As advanced mobile phones become, the more people who do not have access to the mobile environment also takes a hit, since the materials needed to construct mobile phones, when they are no longer needed, require mining.

There will probably be one question like this, which will be worth a large mark. The question will depend on good-quality written communication. The question is most likely to be about environmental issues.

There are some guidelines you can follow for such questions:

- Plan your answer, rather than jumping straight in. The model answer above shows a plan for each side of the discussion, and each paragraph makes several points.
- Know your subject – It is unlikely that you will score highly on a topic you have not written your answer is.
- Read/watch the news – this question is likely to be quite current, and being up to date on developments might give you more to write about.
- Provide examples to support any points you make. (The examples above include satellite navigation).
- Proofread your finished answer. A spelling error (or even a hurriedly corrected one) could be made out, and that mark could put you on the grade boundary.

PROTECTED

Glossary

| Term | Definition |
|--------------------------------|--|
| Abstraction | The practice of hiding layers of complexity within a problem specific aspect. |
| Algorithm | A series of instructions to solve a problem. |
| Analogue | Signals that are continuously variable, i.e. the midpoint between how close together, can be represented. |
| Application software | Programs launched by the operating system to allow the user to perform specific tasks. |
| Arithmetic Logic Unit | A component of the CPU that performs calculations and controls the flow of data. |
| Arithmetic operation | Performs a numeric operation, such as addition or multiplication. |
| Array | A data type in which multiple data items of the same type are stored in a single memory location. |
| Artificial intelligence | The branch of computing where technology attempts to perform tasks that normally require human intelligence. |
| ASCII | A character set consisting of 128 characters. |
| Assignment | The practice of providing a value to a variable. |
| Authentication | The process of ensuring that a user of a system is who they claim to be. |
| Binary | A number system comprising two symbols: 0, 1. |
| Binary search | A search algorithm that begins in the middle of a sorted data set and repeatedly divides the data items with each item that it examines. |
| Binary shift | Moving the digits of a binary number to the left (to multiply by two) or to the right (to divide by two). |
| Biometric | Any piece of data obtained from a person's physiology, such as a fingerprint or retina scan. |
| Bit | The smallest unit of binary data – a binary digit – which can be either 0 or 1. |
| Boolean | A data type that can store one of two values – true or false. |
| Boolean logic | Determining whether an output is true or false, based on Boolean values and operations such as AND, OR, NOT. |
| Boolean operator | Used upon Boolean values (true or false) to produce other Boolean values. Examples include AND, OR, NOT. |
| Boundary data | Test data that represents the highest or lowest permissible values for a variable. |
| Bubble sort | A sorting algorithm that works by repeatedly comparing pairs of adjacent data items and swapping them as necessary. |
| Bus | A connection between computer components, along which data is transferred. |
| Byte | A sequence of eight bits. |
| Cache | Memory with shorter response times than RAM, so used to store recently used data or instructions. |
| Calling | The process of telling a subprogram to take place from elsewhere in the program. |

INSPECTION COPY

COPYRIGHT
PROTECTED

| Term | Definition |
|---|---|
| CAPTCHA | An image of distorted text, readable to humans, but difficult for machines. It is intended to ensure that a human being is using an application. |
| Casting | The process of converting data of one type to be stored in a different type. |
| Central Processing Unit (CPU) | A computer component that performs calculations and controls the execution of instructions. |
| Character | Either a single letter (upper or lower case), a single numeral, or a single invisible character (such as a tab or space). Most keyboards have 256 characters. |
| Character set | All of the characters available within a particular system, each with its own individual code. |
| Clock | A component of the CPU that synchronises activities. |
| Cloud storage | A storage system that takes place remotely, on some managed computer system. |
| Colour depth | The number of distinct colours available (though not necessarily used). |
| Comment | A plain English line (or multiple lines) added to program code to explain it to the computer but is useful to other programmers. |
| Compiler | A translator that translates an entire program before running it. |
| Compression | The process by which a file is made smaller in order to be stored or transmitted more efficiently. |
| Computer Misuse Act | A law that makes unauthorised access of a computer system a criminal offence. |
| Condition-controlled iteration | A program structure in which a section of code repeats until a certain condition is met. |
| Constant | A named location in memory capable of storing a single data item that does not change during program execution. |
| Control Unit | A component of the CPU that coordinates the activity of other components. |
| Copyright, Designs and Patents Act | A law that provides protection for intellectual property, such as software. |
| Core | A processing unit with a control unit, arithmetic logic unit, and cache. A system can have one or more cores. |
| Count-controlled iteration | A program structure in which a section of code repeats a certain number of times. |
| Data Protection Act | A law that governs how personal information is stored and processed. |
| Database | A collection of related data items stored systematically in a computer system. |
| Decimal | A number system comprising 10 symbols: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9. |
| Decomposition | The practice of taking a larger problem and dividing it into smaller, more manageable problems. |
| Defragmentation | Reordering the contents of a disk so that a file is stored, as a single block, rather than in pieces across the disk. |
| Digital | Signals that are comprised of only 1s and 0s, with nothing in between. |

COPYRIGHT
PROTECTED

| Term | Definition |
|--|---|
| Efficiency | In the context of algorithm design, a measure of the amount of time an algorithm uses. If algorithm A is more time efficient than algorithm B, it takes less time to accomplish the same objective. |
| Embedded system | A computer that forms part of a larger electrical or mechanical system. |
| Encryption | The process of converting data into a code, thereby preventing unauthorized access. |
| Erroneous data | Test data that should not be accepted by a system – it is type of data that appears as and when they are supposed to appear. |
| Ethics | The practice of determining right from wrong, often in computing. |
| Fetch-execute cycle | The process by which instructions are run by a computer; instructions are fetched from memory, decoded, and executed (carried out), in a cycle. |
| Firewall | Hardware or software technology that filters network traffic between a network or an individual computer. |
| Flowchart | A diagrammatic means of representing algorithms, using shapes and arrows. |
| Foreign key | The primary key from another table, used in order to create a relationship between two tables. |
| Gigabyte | One billion bytes or one thousand megabytes. |
| Global variable | A variable declared outside of any subroutines, so is visible to all subroutines. Variables continue to exist until the program terminates. |
| Hardware | The physical components of a computer system. |
| Hexadecimal | A number system comprising 16 symbols: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F. |
| High-level programming language | A programming language in which one instruction can translate many machine instructions. Examples include Python, Java and Visual Basic. |
| Hosting | Storing a website, and related items, in such a way that it can be accessed over the Internet. |
| Huffman encoding | A form of compression that represents commonly used character sequences with shorter codes than other characters, thus reducing the file size. |
| Input | The process of introducing data into a computer system, such as via a keyboard or mouse. |
| Integer | A data type comprising whole numbers, including positive, negative and zero. |
| Interface | Completely distinct from 'user interface', this describes how a system communicates with other subsystems. |
| Internet | A network that spans the globe, connecting together a huge number of smaller networks. |
| Internet Protocol (IP) address | A series of four numbers that uniquely identifies each device that is connected to the Internet. |
| Interpreter | A translator that translates and executes line by line. |
| Iteration | A program structure in which a section of code might be executed repeatedly, typically due to a FOR, WHILE or UNTIL statement. |
| Kilobyte | One thousand bytes. |
| Linear search | A search algorithm that begins at one end of a data structure and checks each element in turn until the desired item is found. |
| Local Area Network (LAN) | A series of interconnected devices over a small geographic area, such as a home or a campus. |

| Term | Definition |
|---------------------------------------|--|
| Local variable | A variable declared within a subroutine, which is only accessible within that subroutine. It ceases to exist when the subroutine ends. |
| Logic error | An error in which code runs but produces the wrong output. Often, an incorrect arithmetic operator is used. |
| Low-level programming language | A programming language in which one instruction translates to one machine instruction. Assembly and machine code are low-level languages. |
| MAC address filtering | Blocking traffic onto a network based on the MAC address (unique identifier for a particular computer) from which it is generated. |
| Magnetic | A category of storage in which data is stored in the form of magnetisation on a physical medium. |
| Malware | Any piece of software that causes harm to a computer system, such as viruses, trojans, and ransomware. |
| Megabyte | One million bytes or one thousand kilobytes. |
| Memory | Any means by which a computer stores data for immediate use. This includes memory, cache and registers. |
| Merge sort | A sorting algorithm that divides a data structure into individual elements, sorts the data into pairs, then groups of four, groups of eight, etc. |
| Misuse | Any attempt to use a system in some way other than how it was intended to be used. |
| Modularisation | The process of breaking a program into smaller parts called modules. |
| Monochrome | Describes an image where only varying tones of one colour are used. |
| Nesting | Placing one program structure, such as a loop or selection statement, inside another. |
| Number base | The number of unique digits available in a given numbering system. The decimal system is also known as base-10, because there are 10 distinct symbols. |
| One-dimensional array | An array in which each element is identified by a sequential index. |
| Operating system | The software that manages the hardware, from which applications can be launched. |
| Operator | A symbol used to represent an operation performed on one or more operands. |
| Optical | A category of storage in which data is read and written using light. |
| Output | The process of communicating data beyond a computer system. |
| Parameter | A piece of data that can be passed into a subprogram. |
| Penetration testing | Simulation of a cyberattack on a computer system, in order to identify weaknesses that they are discovered by hackers. |
| Personal Area Network (PAN) | The network of connected devices around a single person, usually used for communication. |
| Pharming | Redirecting web traffic to an unsafe site, typically that closes down the legitimate site. |
| Phishing | Obtaining personal data or login credentials by presenting a fake website or service that people trust. |
| Pixel | The smallest unit within an image; can be considered a dot of a specific colour, and cannot be subdivided. |
| Post-check iteration | A looping structure with a Boolean condition at the end to check if the loop should execute again. |

| Term | Definition |
|-----------------------------------|--|
| Pre-check iteration | A looping structure with a Boolean condition at the start to within the loop should execute. |
| Primary key | A field in a database table used to uniquely identify each record. |
| Protocol | A set of rules governing how data is transmitted across a network. |
| Pseudocode | A cross between English and a programming language, used to write algorithms. |
| Random | A random number has been selected from a range of numbers, where each number in the range had an equal chance of being selected. |
| Random Access Memory (RAM) | Also known as primary storage, it is used by the operating system and applications. |
| Read-only memory | Any memory that can only be read from but not written to. |
| Real number | A type of number comprising numbers that can include fractions; typically represented by a decimal point. |
| Record | A data structure in which multiple data items of different types are stored together. |
| Register | A low-capacity data store – typically 32 or 64 bits – that forms part of a processor. |
| Relational operator | Used to compare two values to see which is larger, or whether they are equal. |
| Resolution | In the context of computer images, the number of pixels that make up the image, described in terms of height and width. |
| Return | The last instruction that executes within a function, which sends data back to the caller of that function. |
| Run length encoding | A form of encryption that maps a data item to the number of times it occurs in a sequence. |
| Sample resolution | The number of bits that make up each sample of a sound. |
| Sampling rate | The number of times per second a sound is sampled by a device. |
| Scope | The visibility of a variable, typically global or local. |
| Search | An algorithm used to determine whether a particular data item exists in a data structure, and often its position within that data structure. |
| Secondary storage | Non-volatile storage (i.e. storage that does not require constant power) used for applications that are not currently in use. |
| Selection | A program structure in which one of two or more paths can be chosen, typically determined by the evaluation of an IF statement. |
| Sequence | A program structure in which each instruction occurs once in a specific order. |
| Social engineering | Exploiting people as the weakness in any computer system. |
| Software | The programs that run on a computer system. |
| Solid state | A category of storage that stores data electronically, with no moving parts. |
| Sort | An algorithm used to place data items into some kind of order, such as alphabetical or numeric. |
| Spyware | Software that covertly obtains sensitive data. |

| Term | Definition |
|---------------------------------------|---|
| String | A data type consisting of a sequence of characters. |
| Structure Query Language (SQL) | A language for reading and altering the contents of a database. |
| Subroutine | A named out-of-line set of instructions that forms part of a program. |
| Syntax error | An error that comes from failing to follow the rules of grammar in a programming language. |
| System software | Programs that are needed for effective communication with hardware and launching application software. |
| TCP/IP model | A layered set of common communication protocols. |
| Terabyte | One trillion bytes, or a thousand gigabytes. |
| Topology | The physical layout of a network – where components are connected to each other. |
| Trace table | A table used to track the values of variables as an algorithm runs. |
| Translator | A piece of software that converts source code (written by a programmer) into machine code (executable by the computer). |
| Trojan | A legitimate program designed to conceal malicious code within it. |
| Truth table | Maps all possible combinations of Boolean inputs to the output of a given function. |
| Two-dimensional array | An array in which each element is identified by a pair of indices. A point on a Cartesian plane can be identified using X and Y coordinates. |
| Typical data | Test data that represents normal use of a system. |
| Unicode | A character set that includes ASCII, as well as many other characters from other alphabets. |
| Unpatched software | A program that has a security vulnerability that has not been 'patched' (which is an update, typically written by the software developer, to fix the vulnerability). |
| User interface | The means by which a human and a computer interact with each other. |
| Utility | An application that maintains a computer in some way, such as defragmenting a hard drive. |
| Validation | The process of ensuring that data entered into a system is correct and meets the requirements. |
| Variable | A named location in memory capable of storing a single data item. |
| Virus | Self-replicating code that causes damage to a computer system. |
| Von Neumann architecture | A means of organising a computer system in which both data and instructions are stored in the same memory, and data and instructions use a common bus to move between the memory and the processor. |
| Wide area network | A network of interconnected devices over a large geographic area, spanning multiple countries. |
| Wire | A means of connection on a network that uses wires, such as Ethernet. |
| Wireless | A means of connection on a network that does not use wires, such as Wi-Fi. |
