Product Support from ZigZag Education	i	Section 3 – Standard Computing Algorithms	16
Terms and Conditions of Use	ii	Task 3.1 – Bubble Sort	16
Teacher Introduction	1	Task 3.2 – Merge Sort	16
Student Introduction	2	Task 3.3 – Insertion Sort	16
Section 1 – The Basics	3	Task 3.4 – Quick Sort	16
Task 1.1 – The RANDOM Function	3	Task 3.5 – Sort Comparison	17
Task 1.2 – Variables	3	Task 3.6 – Linear Search	17
Task 1.3 – Concatenation	4	Task 3.7 – Binary Search	17
Task 1.4 – Arithmetic	4	Task 3.8 – Search Comparison	17
Task 1.6 – WHILE Loop	4	Task 3.9 – Stacks	18
Task 1.5 – FOR Loop	4	Task 3.10 – Queues	18
Task 1.7 – DO UNTIL Loop	4	Task 3.11 – Trees (harder)	18
Task 1.8 – IF THEN ELSE	4	Task 3.12 – Graphs; Dijkstra’s Shortest Path Algorithm (harder)	19
Task 1.9 – Boolean Operators	5	Section 4 – Games	20
Task 1.10 – CASE/SWITCH	5	Game 1 – Simple Guessing Game	20
Task 1.11 – String Manipulation	5	Game 2 – Mix Up Fruit and Veg	20
Task 1.12 – Arrays	6	Game 3 – Hangman	20
Task 1.13 – 2D Arrays	6	Game 4 – Maths Challenge	21
Task 1.14 – Character Codes	7	Game 5 – Quiz	21
Task 1.15 – Procedures	7	Game 6 – Rock Paper Scissors	21
Task 1.16 – Functions	8	Game 7 – Higher or Lower	22
Task 1.17 – Files	8	Game 8 – Tic-Tac-Toe	22
Task 1.18 – Input	9	Game 9 – Pairs	22
Section 2 – Common Practice Tasks	10	Game 10 – Minesweeper	23
Task 2.1 – Hex Colours	10	Pseudocode Solutions for Sections 1 and 2	24
Task 2.2 – Logic Gates	10	Section 1 – The Basics	24
Task 2.3 – What Grade Did I Get?	11	Section 2 – Common Practice Tasks	33
Task 2.4 – Binary Hex	11	Pseudocode for Minesweeper Game	44
Task 2.5 – Weight Converter	12	Flowcharts for Sorting Algorithms	46
Task 2.6 – How Much Change?	12	Insertion Sort	46
Task 2.7 – Table Transposition	13	Bubble Sort	46
Task 2.8 – Quadratic Solver	14	Merge Sort	47
Task 2.9 – Email Checker	14	Quick Sort	48
Task 2.10 – Maze Creator (harder)	15	Appendix: Python ‘Cheat Sheet’	49

Teacher Introduction

Through these tasks, beginner and intermediate programming students develop their skills to the level where they create a mini-games website. The exercises are arranged in increasing difficulty for students to complete in order. Intermediate students should find the initial exercises a very quick refresher. These challenges are also suitable for practising drawing flow diagrams and creating pseudocode solutions.

Although not essential, I recommend that students work through these in order, as most of the challenges use programming techniques learnt in previous challenges. If students are stuck on some of the more involved challenges, then one option is to provide them with the pseudocode solutions. You may want to leave out a couple of the more advanced challenges, such as the maze creator trees and graphs marked '(harder)', for all but the most motivated students below Year 12.

Also see the advice to students about using AI, in the student notes.

Please do send us suggested improvements – if we make changes as a result we will send you an updated copy.

Solutions, Pseudocode and Flowcharts

The source code for the solutions to all 50 algorithms is provided in Python 3.10. See details below to download them. It also includes a folder for playing cards images to be used for the 'Pairs' and 'Higher or Lower' game challenges.

Pseudocode solutions are provided to all 28 basic and common practice tasks in sections 1 and 2, and to the Minesweeper game algorithm. You could set your students to write the pseudocode for the tasks before they start coding.

Flowcharts are provided for the four sorting algorithms; again, students could be asked to create the flowcharts before they start coding, or to work through them to understand how they work, or they could be asked to convert the flowcharts to pseudocode.

There will be multiple ways to solve longer challenges. Credit should be given for working solutions that meet the requirements. Students that finish tasks earlier than others can be challenged to compare solutions with others and to find the most efficient solution, as this is also an important skill to develop.

November 2025

Electronic files for this resource are provided on the ZigZag Education Support Files system, which can be accessed via zzed.uk/productsupport

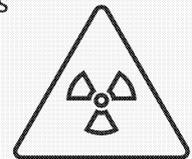

Student Introduction

This set of tasks is intended for you to learn through doing. It can be used by someone with no experience of programming. If you already have some programming experience you should still do all the tasks but will find them super-quick to do, until you find your level.

It is important to add comments and indentation to make your code easier to read. At the end of each task compare your code to the example solution. There is rarely a 'best' solution, but when you compare your code to other students' code and to the example solution, think about a balance of the following points:

- Which code is right and always gives the right result?
- Which code caters for erroneous input and never crashes?
- Which code runs the fastest?
- Which code is the easiest to read, well-structured and with concise comments where appropriate, and therefore is easiest for someone else to make changes?
- Which code didn't take too long to write?

Of course, many of the algorithms can be found on the Internet, and AI sites such as ChatGPT and Gemini will write solutions to most of them. However, resist using them as it defeats the object of you learning to code and gaining experience of coding. Once you are experienced at coding you can then learn how to use AI to greatly speed up your coding, along with the different ways to use it, and its weaknesses.

If your teacher allows you access to AI, we recommend you use it in these ways:

1. When you are struggling to debug a line – ask the AI what is wrong with it.
2. When you have finished and tested your program, ask the AI if there are any problems with your code and how it could be improved.
3. Ask the AI how your code can be optimised to make it faster.
4. Ask the AI how your code can be made more readable.

Create a menu to link to each of your solutions. If you are using a web-based programming language such as PHP, then create an HTML index page with links to your solutions and at the end of each solution add a link back to the menu.

Section 1 – The Basics

This collection of 18 short tasks covers all the basic programming constructs. If you are able to do all of these, using any basic programming book or website for the help (see the *cheat sheet* at the end of this resource). If you already have experience of coding, whizz through this section at high speed.

Either way, take a small amount of extra time to do:

1. Ensure your code is readable with indentations, spacing and the occasional comment.
2. Give clear user instructions on the screen and present things clearly.
3. Test your code with a debugger for erroneous user input.

Task 1.1 – The RANDOM Function

Task

Output each of the following on a new line:

- A random whole number from 0 to 10 inclusive
- A random whole number from 50 to 100 inclusive
- A random number from 0 to 10 inclusive, to 2 decimal places

You should find that each time you run the program you get different numbers.

Hints

- ❖ If you get the same number every time then you are using a programming language which does not generate random numbers.
- ❖ Some languages automatically print out a new line (sometimes called a return), e.g. in Python. Some languages like VB.NET have an option for with and without a new line but `write()` does not. In some languages, like JavaScript, you put `\n` at the end of a line. Finally, if your output is in HTML (e.g. from PHP) then you can either use `
` or the paragraph in `<P>...</P>`.

Task 1.2 – Variables

Task

A variable holds data, and it can change:

- Put a random number from 0 to 10, inclusive, into a variable called *random1*.
- Put a random number from 1,000 to 2,000, inclusive, into a variable called *random2*.
- Output both variables and then output the total of the two variables added together on a new line.

INSPECTION COPY

COPYRIGHT
PROTECTED

Task 1.3 – Concatenation

Task

Store the strings “super”, “fast”, “fly” in three variables, concatenate them with spaces between them, and output the result.

Notes

Concatenation means joining strings together; for example, concatenating the strings “house” and “boat” creates the string “houseboat”. Alternatively, if you concatenate the strings “house”, “ ”, and “boat”, this creates the string “house boat”.

Hints

- ❖ PHP concatenation
e.g. `echo "house boat";`
- ❖ Python concatenation
e.g. `print("house boat");`
- ❖ JavaScript concatenation
e.g. `console.log("house boat");`

In some languages you can concatenate different types of variables together, e.g. strings and Booleans. In other languages you have to convert other data types to strings before concatenating.

Task 1.4 – Arithmetic

Task

Generate a random number between 1 and 100 inclusive, and another between 1 and 100 inclusive, with an explanation of what each number is:

- The two numbers added together
- The second number subtracted from the first number
- The two numbers multiplied together
- The first number to the power of the second number
- The first number divided by the second number
- The first number and remainder when the first number is divided by the second number

Task 1.5 – FOR Loop

Task

Output the numbers 1 to 10 using a *FOR loop*, on one continuous line, with a space between each number.

Task 1.6 – WHILE Loop

Task

Output the 17 times table from 1 to 17,000, using a *WHILE loop*.

Task 1.7 – DO UNTIL Loop

Task

The Fibonacci series begins with 1, 1, 2, 3, 5, 8, ...

It starts with two 1s, then each subsequent number is the sum of the previous two numbers.

Output the Fibonacci series using a *DO UNTIL loop*, until you get to over 1,000.

Task 1.8 – FOR Loop

Task

Iterate through (loop) from 1 to 1,000. If the number is both 5 and 7 then output an asterisk. Output on one continuous line.

**COPYRIGHT
PROTECTED**

Task 1.9 – Boolean Operator

Task

A student has taken two tests out of 50. Generate two random test scores between 0 and 50.

- If either one of the scores is above 30 then output “Well done, you passed”
- If both scores are above 30 then output “Very impressive, you have passed with flying colours”
- If neither score is above 20 then output “Simply NOT good enough”

Run your code repeatedly until you have seen all outcomes.

Task 1.10 – CASE/SWITCH

Task

Generate a random number from 1 to 7. Use a case statement to output whether it is a weekday, a Saturday or a Sunday, where 1 = Monday, 2 = Tuesday, etc.

Hint

Some languages call this a *switch* statement. If you are using a language that supports a *match-case* statement, that is also fine.

Task 1.11 – String Manipulation

Task

Using the two real words *uncharted* and *hippopotomonstrosesquipedalian*:

1. Combine the first 5 characters of the first word and the last 5 characters of the second word.
2. Combine the first 5 characters of the first word and the last 5 characters of the second word.
3. Combine:
 - a. 5 characters from the first word starting from the 3rd character with the last 5 characters of the second word.
 - b. 5 characters from the second word starting from the 15th character with the last 5 characters of the first word.
4. Combine:
 - a. 4 characters from the second word starting from the 20th character with the last 4 characters of the first word.
 - b. 6 characters from the first word starting from the 12th character and the last 4 characters of the second word.
 - c. 4 characters from the end of the second word with the last 4 characters of the first word.

Print out the two original words and the four new words. Calculate and display in brackets, after each of the six words, how many characters are in each word.

Hint

Most programming languages have a function to get the length of a string.

INSPECTION COPY

**COPYRIGHT
PROTECTED**

Task 1.12 – Arrays

Task

Here is an array of numbers: [34, 7, 12, 45, 99, 2, 88, 66, 23, 18, 56, 9, 91, 42]

Your task is to:

1. Separate the odd and even numbers into two different arrays.
2. Display how many numbers are in each of the arrays.
3. Display the sum of the odd and even numbers.
4. Sort the odd and even arrays into ascending order and display them.

Notes

- ❖ To work out if a number is odd or even, calculate the remainder when divided by 2 and see if it equals 0. If the remainder is 0, the number is even, otherwise it is odd.
- ❖ In most programming languages, a loop goes from 0 to n-1.

Task 1.13 – 2D Arrays

Task

Here is a classroom seating arrangement.

Row 1	Ayesha
Row 2	James
Row 3	Theo
Row 4	Sophia

Create a 2D array that represents this classroom seating arrangement, where each row in the array corresponds to a row of seats in the classroom, and each column corresponds to a seat in that row.

- Display the seating arrangement with student names.
- Count and display the number of students, the number of empty seats, and the total number of seats in the classroom.
- Display a linear representation of the seating arrangement of the names with row and column indices.

Notes

In Python, you can create a 2D array like this:

```
matrix = [
    [1, 2, 3],
    [4, 5, 6],
    [7, 8, 9]
]
```

Rows and columns start at 0. You can output any item by referencing its row and column index. e.g. `print(matrix[1][1])` would output 5.

COPYRIGHT PROTECTED

Task 1.14 – Character Code

Task

Create a random password made up of:

1. 4 random capital letters
2. 4 random numbers
3. 4 random lower-case letters
4. 4 random characters from an array of special characters: £, \$, %, ^, & and *

Display the random password in the console. Then convert and display the same random password in all upper case.

Hints

- ❖ a-z are characters
- ❖ A-Z are characters

Notes

Example Python commands for manipulating strings:

```
sentence = "hello WORLD"
print(sentence.lower()) # Output: hello world
print(sentence.upper()) # Output: HELLO WORLD
print(sentence.capitalize()) # Output: Hello world
print(sentence.title()) # Output: Hello World
print(len(sentence)) # Output: 11
print(sentence.replace(" ", "")) # Output: helloWORLD
```

Task 1.15 – Procedures

Task

Create a procedure which outputs the information from any 2D array in an HTML table. The first row should be a shaded heading row (no matter how many columns the array).

Time Slot	Monday	Tuesday	Wednesday	Thursday	Friday
9:00 - 10:00	Maths	English	Science	History	Art
10:00 - 11:00	Physics	Biology	Maths	English	PE
11:00 - 12:00	Chemistry	Geography	Physics	Art	Science
12:00 - 1:00	Lunch	Lunch	Lunch	Lunch	Lunch
1:00 - 2:00	History	Science	PE	Maths	English
2:00 - 3:00	Art	History	Biology	Geography	Physics

Create an array of the information above and pass it into your procedure.

If your code is not being run in a web browser, then save the output to an HTML file and view it in a browser to check your output.

Hint

In some languages there is a function that does this.

Notes

Example Python procedure:

```
def print_stars(x):
    #Prints x stars in a row.
    print("*" * x)
```

```
# Example usage:
print_stars(5) # Output: *****
print_stars(10) # Output: *****
```

- **def** is used to define a procedure
- **x** is a parameter — it takes in a value
- Note how ***** (the multiply symbol) is used in strings in Python ("*" * 5 → "*****")

**COPYRIGHT
PROTECTED**

Task 1.16 – Functions

Task

In maths, $5!$ means 5 factorial, which means $5 \times 4 \times 3 \times 2 \times 1 = 120$.

- Create a function called *factorial1* which is given a number and returns the factorial using a loop.
- Create a recursive function called *factorial2* that works out and return the factorial.
- Write a program which works out $170!$ using both methods and displays the result (to 6 decimal places).

Computers are getting increasingly powerful, and different languages will do this with more or less efficiency. If $170!$ takes too long to calculate, or is too quick to register a result, then increase the number.

Notes

Example Python function:

```
def greet(name):
    return "Hello, " + name + "!"
```

```
# Call the function
greeting = greet("Alice")
print(greeting)
greeting = greet("Bob")
print(greeting)
```

- **def** is used to define a procedure or function.
- **name** is a parameter — it takes input.
- The function is called using its name.

Task 1.17 – Files

Task

Create a secret message to a friend, then:

- Write a function to encode any string into a coded message by reversing the string.
- Write a function to decode the string.
- Save the secret message to your friend in a variable.
- Encode the message and save the coded message to a file called 'top-secret.txt'.
- Read the file back in, decode it, and output it.
- Check that the file has been properly created.

Hint

Ensure you output the message if the file doesn't exist. What happens if the file doesn't have the message?

**COPYRIGHT
PROTECTED**

Task 1.18 – Input

Task

- Prompt the user to type two numbers.
- Ensure they are integers and multiply them together.
- Output the result.

Notes

You can use the command line for input, or you can use a form to input numbers with two input text boxes and one button, like the example shown here.

Multiplication

Please enter two numbers below

First Number :

Second Number :

Hint

You will need to check that the input fields are not empty.

INSPECTION COPY

INSPECTION COPY

INSPECTION COPY

COPYRIGHT
PROTECTED

Section 2 – Common Practice

Each of the following exercises are common challenges to face and are an opportunity to practice using the programming constructs from section 1.

Task 2.1 – Hex Colours

Task

An HTML colour code is made up of three colours: red, green and blue. Each colour is represented by a number from 0 to F (from 0 to 15 in decimal), where 10 is A, 11 is B, 12 is C, 13 is D, 14 is E and 15 is F. The colours are, therefore, written as hexadecimal numbers from #000000 to #FFFFFF.

Output a table that displays all the colours where each of the three colours is a decimal number from 0 to 15. The first colour is #110000, #220000, up to #FFFFFF.

Notes

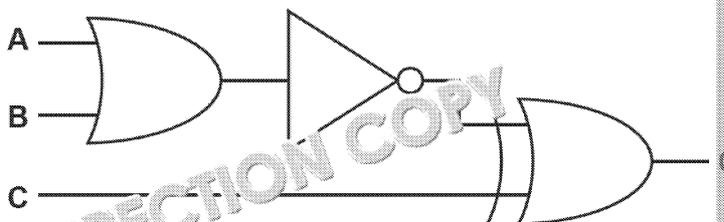

- Create a function that takes in three integers from 0 to 15 and converts them to hexadecimal, then concatenates them with a # at the front.
- Table cells can have a background colour which is set with the hexadecimal number.
- Rotate through all the possible combinations of x, y and z being the numbers 0 to 15, and output them in a table cell with the background colour set to the hexadecimal number.
- Use a CSS `<style>` command to create styling for your table cells.

If your code is not being run in a web browser, then save the output to an HTML file and check your output.

- ❖ Use three nested loops to loop through all the different combinations.
- ❖ You will need to know or look up how to create HTML tables for this task.
- ❖ If coding in PHP or other web-based language, you don't need to use a for loop.

Task 2.2 – Logic Gates

Task

Output the truth table for the logic circuit shown above.

INSPECTION COPY

COPYRIGHT
PROTECTED

Task 2.3 – What Grade Did I Get?

Task

- Create a function called *printgrade* which is passed the percentage and returns a sentence that says 'Grade x achieved', where x is the grade, based on the following table. It should accept the input as a decimal number, e.g. 78.5.
- Ask the user to enter their mark out of 100 and then give them their resulting grade.

Hints

- ❖ Don't use multiple *if* statements to calculate the grade; use a *case* statement if the language has it. For example, PHP has a *switch case* statement and Python has a *match* statement.
- ❖ When your code is working, do some testing by typing in marks in each grade range and check it works perfectly.
- ❖ Even if you limit your text box to accept numbers only, it is still a good idea to check that if something goes wrong it doesn't crash your program.

Task 2.4 – Binary Hex

Task

Ask the user to type in a decimal number. Work out and output the number as a binary number and as a hexadecimal number.

Manually convert the decimal to binary with your own algorithm; do not use an inbuilt function, otherwise you are not learning all the skills you need. (You can, however, use inbuilt function, if there is one, to convert from binary to hexadecimal.)

Test your program with 3819 and check you get the same results as shown here.

Binary Hex

Please enter a number: 3819

submit

Decimal number: 3819

Binary: 111011101011

Hexadecimal: EEB

Hints

- ❖ Most programming languages have a function to convert from binary to hexadecimal. For example, in PHP you can use the inbuilt *hexdec(bindec(\$value))* function. In Python you can use *hex(int(binary, 2))[2:].upper()*, which converts the binary string to an integer, and then to a hexadecimal string.
- ❖ Plan what extreme and error values might be entered and cater for these in your program. For example, 2,000,000 and 2,000,000,000 give the right answers.

**COPYRIGHT
PROTECTED**

Task 2.5 – Weight Converter

Task

Ask the user to choose between entering a weight in stones and pounds to display in kilograms or entering a weight in kilograms to display in stones and pounds.

Hints

- ❖ $10 \text{ kg} = 2.0 \text{ stone}$
- ❖ $1 \text{ stone} = 14 \text{ pounds}$
- ❖ Note that there are 14 pounds in a stone
- ❖ You will need to use the MOD function
- ❖ In the attached web-based screenshot, the program will need to know which 'Convert' button has been pressed

How Heavy?

Please enter a weight in stones and pounds:

Please enter a weight in kilograms:

64 kg = 10 stone 1.09568 lb

Task 2.6 – How Much Change?

Task

Assuming a customer has paid with a £20 note, and that they are purchasing an item, ask the user to enter the cost of the item and calculate the change. The customer should receive individual notes and coins.

For example, if an item costs £14 then the change from a £20 note would be £6. This would be a £5 note, a 50p coin and a 1p coin.

Hints

- ❖ If the total change is more than £10 then they will get a £10 note, which you subtract from the change and then repeat this check.
- ❖ There might be more than one coin of the same value; for example, an item might cost £1.01, so the change would have $2 \times 2\text{p}$ in the change.
- ❖ This task is a little trickier than it looks on the surface to get the output to be in pounds or pence, and to indicate whether it is a note or a coin.

**COPYRIGHT
PROTECTED**

Task 2.7 – Table Transposition

Task

Set a constant SIZE to be 10. Create a 10×10 array of random numbers between 0 and 9 in an HTML table. Then, flip the array by transposing the rows to columns and the columns to rows again. For example:

9	3	1	6	3	5	4	6	2	1
5	1	0	7	3	6	7	1	0	3
6	2	3	3	7	4	9	0	0	0
7	0	3	3	9	2	2	6	8	8
8	7	6	5	5	6	8	7	2	1
1	5	5	4	6	1	0	8	9	2
0	6	6	4	8	5	4	1	1	1
7	9	0	0	7	6	3	4	9	1
4	9	7	9	2	0	9	6	8	7
4	5	2	5	6	8	5	2	7	2

→

9	5	6
3	1	2
1	0	0
6	7	1
3	3	0
5	6	7
4	5	4
6	1	9
2	0	0
3	3	0

Hints

- ❖ Create a function to generate the array.
- ❖ Create a procedure to create an $n \times n$ array.
- ❖ Create an algorithm to flip an $n \times n$ array; each coordinate (x,y) in the first grid becomes (y,x) in the second.
- ❖ Use a programming language with web output, then create a procedure to display the table.

INSPECTION COPY

COPYRIGHT
PROTECTED

INSPECTION COPY

Task 2.8 – Quadratic Solver

Task

In GCSE maths you have to solve quadratic equations in the form $ax^2 + bx + c = 0$.

For example, solve $2x^2 - 3x + 17 = 0$

One method of solving this is to use the formula $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$

In this example, $a = 2$, $b = -3$ and $c = 17$

Write a program that asks a student for the values of a , b and c , and works out two solutions.

Hints

- ❖ Remember that square root normally gives two answers, which is why the formula has \pm . The square root of 4 is both -2 and +2.
- ❖ If $b^2 - 4ac = 0$, for example if $a = 1$, $b = 2$ and $c = 1$, then there is only one solution.
- ❖ You cannot square root a negative number. For example, if $a = 1$, $b = 1$ and $c = 4$, then $b^2 - 4ac = 1 - 16 = -15$. Therefore, the program needs to check for this and tell the user if it occurs.

Task 2.9 – Email Checker

Task

Ask the user to input an email address and output whether or not it is a valid email address. Explain why.

Here are the rules of what is and isn't allowed in an email address:

- An email address is made up of the local part, followed by @, followed by the domain part.
- The local part must be at least one character including upper- and lower-case letters, digits, and special characters *period (dot)*, *hyphen*, *underscore*, although the special characters cannot appear at the beginning or the end or appear consecutively (h.-h is allowed, but not h..h).
- The domain part must be a combination of alphanumeric characters and hyphens. The hyphens and periods cannot appear at the beginning or end. There must be at least one period in the domain part.
- The domain part must be between 2 and 255 characters, and the overall email address must be between 2 and 320 characters.

**COPYRIGHT
PROTECTED**

Task 2.10 – Maze Creator (harder)

Task

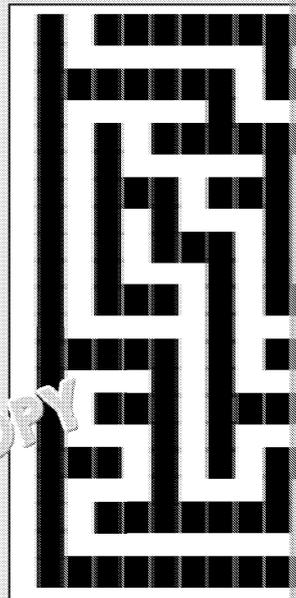

Generate a random maze, that has one solution, based on a grid specified by the user, that is from 11×11 to 49×49 ; the height and width can be different from the *recursive backtracking* logic below on paper first before you start coding.

Hints

- ❖ Only use odd dimensions so that all walls align correctly.
- ❖ Start by making a single block (wall).
- ❖ Start at $(0, 1)$ so that $(0, 1)$ is part of the wall, and end the wall at the bottom right width.
- ❖ Always move 2 steps when creating the maze (so a path doesn't touch another path).

Use *recursive backtracking* to create the maze:

1. Pick a random direction (Right, Left, Down, Up).
2. Check if the next cell (2 steps away) is inside the grid and is a wall (a block).
3. If it is a block, then carve a path by:
 - Converting the target cell into a path (' ').
 - Converting the wall between the target cell and the previous cell into a path (' ').
4. Recursively continue from the new position.
5. Backtrack (end the recursive function) when no more moves are possible.

INSPECTION COPY

Section 3 – Standard Computing

The following algorithms will be found on most GCSE, A Level, BTEC and OCR Tech quite likely you will have an exam question based on one of these, so it is a good listed on the specification you are learning without support, and to understand struggling to understand how any of them work then ask your friend who does to explain you will find many YouTube explanations too.

Tasks 5 and 8 are linked to the concept of the efficiency of different algorithms, in a computing specification.

Task 3.1 – Bubble Sort

Generate an array that contains 50 random integers between 1 and 100. It is fine if some numbers are repeated.

Write a program to put the array in size order using the Bubble sort algorithm, which compares each number with the next, and swapping them over if the first number is larger than the second until all the numbers are in order.

Task 3.2 – Merge Sort

Generate an array that contains 50 random integers between 1 and 100. It is fine if some numbers are repeated.

Write a program to put the array in size order using the Merge sort algorithm, which splits the array into two sub-arrays, sorts them (using merge sort), and then merges the two sub-arrays back together.

Task 3.3 – Insertion Sort

Generate an array that contains 50 random integers between 1 and 100. It is fine if some numbers are repeated.

Write a program to put the array in size order using the Insertion sort algorithm which shifts the array and inserts it in the right place to its left to ensure that the items checked are in order.

Task 3.4 – Quick Sort

Generate an array that contains 50 random integers between 1 and 100. It is fine if some numbers are repeated.

Write a program to put the array in size order using the Quick sort algorithm which chooses a pivot in the middle of the array, then moves the items to the left which are smaller, and to the right which are larger, then performs a Quick sort on each of the sub-arrays on the left and right.

Task 3.5 – Sort Comparison

Generate an array that contains 5,000 random integers between 1 and 10,000. It is fine if some numbers are repeated.

Make five copies of this array. Sort one with a Bubble sort, one with a Merge sort, one with a Quick sort, and the last with the inbuilt sort function for the language you are using. Display the time each sort takes and display the results, to 5 decimal places.

Note

If your computer takes longer than 30 seconds to run this, or is so fast that it displays 0 time, then change the size of the array.

Task 3.6 – Linear Search

Generate an array that contains 100 random integers between 1 and 200. It is fine if some numbers are repeated.

Generate a single random integer and search the array for it using a Linear search. Display whether or not the number is in the array, and which position it is found in.

Task 3.7 – Binary Search

Generate an array that contains 100 random integers between 1 and 200. It is fine if some numbers are repeated. Sort them in order (using any sort).

Generate a single random integer and search the sorted array for it using a Binary search. Display whether or not the number is in the array, and which position it is found in.

Task 3.8 – Search Comparison

Generate an array that contains 500,000 random integers between 1 and 100,000. It is fine if some numbers are repeated. Sort the array in order.

For each number between 1 and 10,000, search for it in the sorted array using each of the following: Binary search, and the inbuilt search array function. Display to the user how long each search takes. Do 10,000 searches.

Why, sometimes, does the Binary search give a slightly different result from the inbuilt search?

Note

If your computer takes longer than 30 seconds to run this, or is so fast that it displays 0 time, then change the size of the array.

PROTECTED**

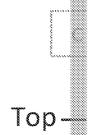

Task 3.9 – Stacks

Create a program that manages a stack where users can **push** an item onto a stack or **pop** the top item off the stack, displaying the updated stack each time.

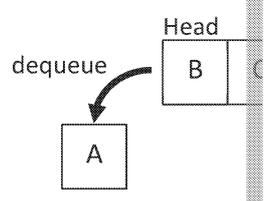

Also give the option to **peek**, which means to display the current top item on the stack.

The program should continue running until the user opts to exit.

Task 3.10 – Queues

Create a program that manages a queue where users can **enqueue** (push) an item onto the tail of a queue or **dequeue** (pop) the head item off the queue, displaying the updated queue each time.

Task 3.11 – Trees (harder)

Implement a simple tree structure, where each item (node) in the tree has a name and a root node with ID 1. All nodes refer to:

- Add a new node to any other node by giving the name and ID of the parent.
- Remove a node (and all its children if it has any).
- Use an HTML form to provide an interface for interacting with the tree.

Once you have it working, test it by:

- Adding some nodes under the "Root" node.
- Adding child nodes under nodes you have added.
- Removing a node and observing how it affects the tree structure.
- Try adding error handling for invalid parent or node IDs.

Task 3.12 – Graphs; Dijkstra's Shortest Path [harder]

The diagram above shows seven towns (A–G), the main roads between them, and the distances between them. Write a program that:

1. Stores this information in a *graph* data structure.
2. Outputs a table which shows the distances between all the directly connected towns.
3. Prompts the user to enter two towns and then uses Dijkstra's Algorithm to find the shortest path between them.

Section 4 – Games

Now time for a bit of fun! Each of these games is designed to develop your programming skills, uses complex programming skills, and even the hardest can be completed in fewer than 100 lines of code.

Your main focus is to get each game to work properly. Also spend a small amount of time on the presentation. If you are using a web-based programming language such as PHP or Python with HTML output, then use a style sheet in the HTML to make the game look nice.

When you have finished, compare your solutions with the solutions we have provided and compare the differences between them. This will help develop your understanding and skills.

Game 1 – Simple Guessing Game

Task

- Generate a random whole number from 1 to 10.
- Ask the user what they think the number is.
- If they get it right tell them “Well done”, otherwise give them another go, until they get it right.

Game 2 – Mix Up Fruit and Veg

Task

- Create a function called `getWord()` which contains an array of 50 fruits and vegetables and returns one of them at random.
- Randomly shuffle the letters of the word and display it to the user.
- Ask the user to type in the unscrambled word.
- End the game when the user gets it right or after they have had three goes.

Game 3 – Hangman

Task

- Create a function called `getRandomWord()` which contains an array of 80 or more words with between 10 and 15 characters and returns one of them at random. You can use `ChatGPT`, `Gemini` or `Copilot` to generate the words for you.
- Show an underscore (`_`) for each letter of the selected word and prompt the user to enter a letter.
- If the letter is in the selected word, then display the letter in the right place in the word.
- If the letter is not in the selected word, then add it to a displayed list of letters that have been tried.
- If the letter has already been tried, then ignore it.
- The game ends when either the user has guessed all the letters in the word, or has used up all the incorrect letters.

COPYRIGHT
PROTECTED

Game 4 – Maths Challenge

Task

- Create a function called *generateQuestion()* which generates:
 - two random numbers between 1 and 20
 - either the addition, subtraction, division or multiplication operator, at random
 - the answer (if the division operator is picked, then the division must give a whole number)
- Start a timer, then ask the user to answer *n* questions as they can answer in 60 seconds
- Each time they answer a question, tell them whether or not they got it right, and ask for the next question.
- After 60 seconds the user is told how many questions they got right (you can question during which the 60 seconds expired).

Game 5 – Quiz

Task

- Create a function called *getQuizQuestions(howManyQuestions)* which contains an array of at least 20 questions, each with four multiple-choice answers, and where the answer 1, 2, 3 or 4 is correct. The function should return the content of *num* questions requested, at random. If more questions are requested than have been created, return them all.
- For the game, fetch five questions and then show each question, in order, to the user.
- Once they have answered all five questions, give them their score, and show them any of their incorrect answers).

Game 6 – Rock Paper Scissors

Task

- Create a function called *computerGuess()* which returns either “rock”, “paper” or “scissors” at random.
- Ask the user to pick “rock”, “paper” or “scissors”.
- The rule is that “rock” beats “scissors”, “paper” beats “rock”, and “scissors” beats “paper”. It is a draw otherwise. Give one point to the winner, or no points if it is a draw.
- Tell the user what they and the computer picked, and who the winner was of the round.
- The first to get to 5 points wins.
- At the end, tell the user who is the winner.

COPYRIGHT
PROTECTED

Game 7 – Higher or Lower

Task

- Create a function called `getShuffledCards()` which generates 52 items in an array representing a pack of playing cards, i.e. 2–10, Jack, Queen, King and Ace of each of Hearts, Spades, Clubs and Diamonds. It then shuffles the cards and returns the array.
- Your program should then display the first card for the user to suggest whether the next card will be higher or lower. Images for the 52 playing cards are provided with this resource in the format `02_of_clubs.png`, `ace_of_spaces.png`, etc. Convert the filename so you can display the card.
- If the user guesses correctly then the next card is displayed, and the game continues.
- If the next card is the same value (e.g. the 5 of diamonds is worth the same as the 5 of hearts) then the game ends.
- The game ends when either the user is wrong, or they get all of them right, whichever comes first.
- When the game ends, all the cards should be shown, highlighting the cards that were guessed correctly.
- If the user gets more than 10 right, tell them that is excellent. If they get more than 20 right, tell them that is impressive. If they get them all right, tell them that is unbelievable.

Some languages (e.g. Python) require additional libraries to display images. If you cannot install libraries, then create a non-graphical version.

Game 8 – Tic-Tac-Toe

Tic-Tac-Toe is also known as Noughts and Crosses.

Task

- Create a 3×3 grid of buttons (9 buttons in total).
- The players take turns to click on the top whose go it is with an X or O:
 - The first player clicks the square that they want to turn into an X.
 - The second person clicks the square that they want to turn into an O.
 - This process repeats.
- A player wins if they have three O's or three X's in a row, in a column, or diagonally.
- If all nine squares are filled and no player has won, then it is a draw.

Game 9 – Pairs

Task

- Randomly pick eight card filenames out of the possible 52 playing card images. The card names are in the format `02_of_clubs.png`, `ace_of_spaces.png`, etc.
- Display 16 cards face down (made up of eight pairs of the cards you have selected). The back of a playing card is called `back.png`.
- Indicate at the top whether the current player is Player 1 or Player 2.
- The current player clicks on two cards which are turned over. If the two cards match then the player wins a point and the two cards are turned away. If they do not match then, upon clicking, the cards are turned back face down and it is the other player's turn.
- Once all 16 cards are turned over, the players are told who won, and how many points they have.

PROTECTED**

Game 10 – Minesweeper

Minesweeper is a classic logic puzzle game where the objective is to clear a minefield of mines. The minefield is a grid of blank squares, under some of which are mines. To start and it reveals either:

- A number: this number indicates how many mines are adjacent to that square
- A blank space: if a square has no adjacent mines, clicking it reveals a blank space, and squares will also be revealed automatically.
- A mine, in which case the game is over.

You win the game by clicking all the squares that do not contain mines.

Task

Create the game of Minesweeper:

- Create a function which:
 - sets up a 10×10 array representing 100 squares;
 - randomly allocates 15 squares which contain *exploding mines* (populate)
 - populates the rest of the squares with how many mines are next to it (display)
- Display the grid to the player. When they click on a square:
 - If the player clicks on a mine it's game over.
 - Otherwise reveal the square they are on. If it is a blank square (i.e. there are no mines next to it) then reveal all the squares around it. If any of them are blank, repeat the process. The player then has another go.
- When the game is over, whether the game is won or lost, display the complete minefield. Display the mines in red. If the player has lost, then display the squares they didn't get that don't contain mines in green.

Hint

When populating the minefield, you need to check for mines next to it. Use `isValidCell(rowNum, colNum)` when you check a square around it, even if you are off the board.

Pseudocode Solutions for Section 1

A few key notes on the pseudocode solutions:

- We assume that `print()` will not print a new line, and that `println()` will print a separate functions for printing with and without a new line. Some languages print a new line, and in HTML a new line is `
`.
- We have assumed that pseudocode can concatenate strings with numbers. In some languages, there are symbols for concatenation. Python for example uses `+` either convert numbers to strings or use a function to insert variables in strings.

Section 1 – The Basics

Task 1.1 – The RANDOM Function

```
println(random(0,10))
println (random(50,100))
println (random(0,1000) / 100)
```

Task 1.2 – Variables

```
random1 = random(0,10)
random2 = random(1000,2000)
println (random1)
println (random2)
println (random1 + random2)
```

Task 1.3 – Concatenation

```
word1 = "super"
word2 = "fast"
word3 = "fly"
result = word1 + word2 + " " + word3
println (result)
```

Task 1.4 – Arithmetic

```
num1 = random(1,100)
num2 = random(1,10)
println ("First random number from 1 to 100 is " + num1)
println ("Second random number from 1 to 10 is " + num2)
println (num1 + " plus " num2 + " = " + (num1 + num2))
println (num2 + " minus " num1 + " = " + (num2 - num1))
println (num1 + " to the power of " num2 + " = " + (num1 ^ num2))
println (num1 + " * " num2 + " = " + (num1 * num2))
println (num1 + " divided by " num2 + " = " + (num1 / num2))
println (num1 + " divided by " num2 + " = " + (num1 // num2) + " remainder" + (num1 % num2))
```

Task 1.5 – For Loops

```
for (i = 1 to 10)
    print(i)
next
```
